Highlights

This report presents the first information from the 2011 National Survey on Drug Use and Health (NSDUH), an annual survey sponsored by the Substance Abuse and Mental Health Services Administration (SAMHSA). The survey is the primary source of information on the use of illicit drugs, alcohol, and tobacco in the civilian, noninstitutionalized population of the United States aged 12 years old or older. Approximately 67,500 persons are interviewed in NSDUH each year. Unless otherwise noted, all comparisons in this report described using terms such as "increased," "decreased," or "more than" are statistically significant at the .05 level.

Illicit Drug Use

- In 2011, an estimated 22.5 million Americans aged 12 or older were current (past month) illicit drug users, meaning they had used an illicit drug during the month prior to the survey interview. This estimate represents 8.7 percent of the population aged 12 or older. Illicit drugs include marijuana/hashish, cocaine (including crack), heroin, hallucinogens, inhalants, or prescription-type psychotherapeutics (pain relievers, tranquilizers, stimulants, and sedatives) used nonmedically.
- The rate of current illicit drug use among persons aged 12 or older in 2011 (8.7 percent) was similar to the rate in 2010 (8.9 percent).
- Marijuana was the most commonly used illicit drug. In 2011, there were 18.1 million past month users. Between 2007 and 2011, the rate of use increased from 5.8 to 7.0 percent, and the number of users increased from 14.5 million to 18.1 million.
- In 2011, there were 1.4 million current cocaine users aged 12 or older, comprising 0.5 percent of the population. These estimates were similar to the number and rate in 2010 (1.5 million or 0.6 percent), but were lower than the estimates in 2006 (2.4 million or 1.0 percent).
- The number of persons who were past year heroin users in 2011 (620,000) was higher than the number in 2007 (373,000).
- Hallucinogens were used in the past month by 972,000 persons (0.4 percent) aged 12 or older in 2011. These estimates were lower than the estimates in 2010 (1.2 million or 0.5 percent).
- In 2011, there were 6.1 million persons (2.4 percent) aged 12 or older who used prescription-type psychotherapeutic drugs nonmedically in the past month. These estimates were lower than the estimates in 2010 (7.0 million or 2.7 percent).
- The number of past month methamphetamine users decreased between 2006 and 2011, from 731,000 (0.3 percent) to 439,000 (0.2 percent).
- Among youths aged 12 to 17, the current illicit drug use rate was similar in 2010 (10.1 percent) and 2011 (10.1 percent), but was higher than the rate in 2008 (9.3 percent). Between 2002 and 2008, the rate declined from 11.6 to 9.3 percent.

- The rate of current marijuana use among youths aged 12 to 17 decreased from 8.2 percent in 2002 to 6.7 percent in 2006, remained unchanged at 6.7 percent in 2007 and 2008, then increased to 7.4 percent in 2009. Rates in 2010 (7.4 percent) and 2011 (7.9 percent) were similar to the rate in 2009.
- Among youths aged 12 to 17, the rate of current nonmedical use of prescription-type drugs declined from 4.0 percent in 2002 to 2.8 percent in 2011. The rate of nonmedical pain reliever use declined during this period from 3.2 to 2.3 percent among youths.
- The rate of current use of illicit drugs among young adults aged 18 to 25 increased from 19.7 percent in 2008 to 21.4 percent in 2011, driven largely by an increase in marijuana use (from 16.6 percent in 2008 to 19.0 percent in 2011).
- Among young adults aged 18 to 25, the rate of current nonmedical use of prescription-type drugs in 2011 was 5.0 percent, which was lower than the rate in the years from 2003 to 2010. There was a decrease from 2005 to 2011 in the use of cocaine among young adults, from 2.6 to 1.4 percent.
- Among those aged 50 to 59, the rate of past month illicit drug use increased from 2.7 percent in 2002 to 6.3 percent in 2011. This trend partially reflects the aging into this age group of the baby boom cohort (i.e., persons born between 1946 and 1964), whose lifetime rate of illicit drug use has been higher than those of older cohorts.
- Among unemployed adults aged 18 or older in 2011, 17.2 percent were current illicit drug users, which was higher than the 8.0 percent of those employed full time and 11.6 percent of those employed part time. However, most illicit drug users were employed. Of the 19.9 million current illicit drug users aged 18 or older in 2011, 13.1 million (65.7 percent) were employed either full or part time.
- In 2011, 9.4 million persons aged 12 or older reported driving under the influence of illicit drugs during the past year. This corresponds to 3.7 percent of the population aged 12 or older, which was lower than the rate in 2010 (4.2 percent) and was lower than the rate in 2002 (4.7 percent). In 2011, the rate was highest among young adults aged 18 to 25 (11.6 percent).
- Among persons aged 12 or older in 2010-2011 who used pain relievers nonmedically in the past 12 months, 54.2 percent got the drug they most recently used from a friend or relative for free. Another 18.1 percent reported they got the drug from one doctor. Only 3.9 percent got pain relievers from a drug dealer or other stranger, and 0.3 percent bought them on the Internet. Among those who reported getting the pain relievers from a friend or relative for free, 81.6 percent reported in a follow-up question that the friend or relative had obtained the drugs from just one doctor.

Alcohol Use

- Slightly more than half (51.8 percent) of Americans aged 12 or older reported being current drinkers of alcohol in the 2011 survey, similar to the rate in 2010 (51.8 percent). This translates to an estimated 133.4 million current drinkers in 2011.
- In 2011, nearly one quarter (22.6 percent) of persons aged 12 or older participated in binge drinking. This translates to about 58.3 million people. The rate in 2011 was similar to the estimate in 2010 (23.1 percent). Binge drinking is defined as having five or more drinks on the same occasion on at least 1 day in the 30 days prior to the survey.
- In 2011, heavy drinking was reported by 6.2 percent of the population aged 12 or older, or 15.9 million people. This rate was lower than the rate of heavy drinking in 2010 (6.7 percent). Heavy drinking is defined as binge drinking on at least 5 days in the past 30 days.
- Among young adults aged 18 to 25 in 2011, the rate of binge drinking was 39.8 percent. The rate of heavy drinking was 12.1 percent, which was lower than the rate in 2010 (13.5 percent).
- The rate of current alcohol use among youths aged 12 to 17 was 13.3 percent in 2011. Youth binge and heavy drinking rates in 2011 were 7.4 and 1.5 percent, respectively. These rates were all similar to those reported in 2010 (13.6, 7.9, and 1.7 percent, respectively).
- In 2011, an estimated 11.1 percent of persons aged 12 or older drove under the influence of alcohol at least once in the past year. This percentage was lower than in 2002, when it was 14.2 percent. The rate of driving under the influence of alcohol was highest among persons aged 21 to 25 (21.9 percent).
- There were an estimated 9.7 million underage (aged 12 to 20) drinkers in 2011, including 6.1 million binge drinkers and 1.7 million heavy drinkers.
- Past month, binge, and heavy drinking rates among underage persons declined between 2002 and 2011. Past month alcohol use declined from 28.8 to 25.1 percent, while binge drinking declined from 19.3 to 15.8 percent, and heavy drinking declined from 6.2 to 4.4 percent.
- In 2011, 57.0 percent of current underage drinkers reported that their last use of alcohol occurred in someone else's home, and 28.2 percent reported that it had occurred in their own home. About one third (30.3 percent) paid for the alcohol the last time they drank, including 7.7 percent who purchased the alcohol themselves and 22.4 percent who gave money to someone else to purchase it. Among those who did not pay for the alcohol they last drank, 38.2 percent got it from an unrelated person aged 21 or older, 19.1 percent from another person younger than 21 years old, and 21.4 percent from a parent, guardian, or other adult family member.

Tobacco Use

- In 2011, an estimated 68.2 million Americans aged 12 or older were current (past month) users of a tobacco product. This represents 26.5 percent of the population in that age range. Also, 56.8 million persons (22.1 percent of the population) were current cigarette smokers; 12.9 million (5.0 percent) smoked cigars; 8.2 million (3.2 percent) used smokeless tobacco; and 2.1 million (0.8 percent) smoked tobacco in pipes.
- Between 2002 and 2011, past month use of any tobacco product decreased from 30.4 to 26.5 percent, past month cigarette use declined from 26.0 to 22.1 percent, and past month cigar use declined from 5.4 to 5.0 percent. Rates of past month use of smokeless tobacco and pipe tobacco in 2011 were similar to corresponding rates in 2002.
- The rate of past month tobacco use among 12 to 17 year olds declined from 15.2 percent in 2002 to 10.0 percent in 2011, including a decline from 2010 (10.7 percent) to 2011. The rate of past month cigarette use among 12 to 17 year olds also declined between 2002 and 2011, from 13.0 to 7.8 percent, including a decline between 2009 (9.0 percent) and 2011.
- One in six pregnant women aged 15 to 44 smoked cigarettes in the past month during 2010-2011. The rate of current smoking among pregnant women did not change between 2002-2003 (18.0 percent) and 2010-2011 (17.6 percent), while among women aged 15 to 44 who were not pregnant, the rate declined from 30.7 to 25.4 percent.

Initiation of Substance Use (Incidence, or First-Time Use) within the Past 12 Months

- In 2011, an estimated 3.1 million persons aged 12 or older used an illicit drug for the first time within the past 12 months. This averages to about 8,400 initiates per day and was similar to the estimate for 2010 (3.0 million). A majority of these past year illicit drug initiates reported that their first drug was marijuana (67.5 percent). More than one in five initiated with psychotherapeutics (22.0 percent, including 14.0 percent with pain relievers, 4.2 percent with tranquilizers, 2.6 percent with stimulants, and 1.2 percent with sedatives). In 2011, 7.5 percent of initiates reported inhalants as their first illicit drug, and 2.8 percent used hallucinogens as their first drug.
- In 2011, the illicit drug categories with the largest number of past year initiates among persons aged 12 or older were marijuana use (2.6 million) and nonmedical use of pain relievers (1.9 million). These estimates were not significantly different from the numbers in 2010. However, the number of marijuana initiates increased between 2008 (2.2 million) and 2011 (2.6 million).
- In 2011, the average age of marijuana initiates among persons aged 12 to 49 was 17.5 years, which was higher than the average age of marijuana initiates in 2002 (17.0 years).
- The number of past year initiates of methamphetamine among persons aged 12 or older was 133,000 in 2011. This estimate was lower than the estimates in 2002 to 2006, which ranged from 192,000 to 318,000.
- The number of past year initiates of Ecstasy aged 12 or older was similar in 2011 (922,000) and 2010 (949,000), but the number in 2011 increased from 2005 (615,000).

- The number of past year cocaine initiates aged 12 or older declined from 1.0 million in 2002 to 670,000 in 2011. The number of initiates of crack cocaine declined during this period from 337,000 to 76,000.
- In 2011, there were 178,000 persons aged 12 or older who used heroin for the first time within the past year, not significantly different from the estimates from 2009 and 2010. However, this was an increase from the annual numbers of initiates during 2005 to 2007 (between 90,000 and 108,000).
- Most (82.9 percent) of the 4.7 million past year alcohol initiates in 2011 were younger than 21 at the time of initiation.
- The number of persons aged 12 or older who smoked cigarettes for the first time within the past 12 months was 2.4 million in 2011, which was the same as the estimate in 2010 (2.4 million), but higher than the estimate for 2002 (1.9 million). Most new smokers in 2011 were younger than 18 when they first smoked cigarettes (55.7 percent or 1.3 million). The number of new smokers who began smoking at age 18 or older increased from 623,000 in 2002 to 1.1 million in 2011.
- The number of persons aged 12 or older who used smokeless tobacco for the first time within the past year was 1.3 million, similar to the estimates in 2005 to 2010.

Youth Prevention-Related Measures

- The percentage of youths aged 12 to 17 perceiving great risk in smoking marijuana once or twice a week decreased from 54.6 percent in 2007 to 44.8 percent in 2011.
- Between 2002 and 2008, the percentage of youths who reported great risk in smoking one or more packs of cigarettes per day increased from 63.1 to 69.5 percent, but the percentage dropped to 65.5 percent in 2009 and remained steady at 65.3 percent in 2010 and 66.2 percent in 2011.
- Almost half (47.7 percent) of youths aged 12 to 17 reported in 2011 that it would be "fairly easy" or "very easy" for them to obtain marijuana if they wanted some. More than one in six reported it would be easy to get cocaine (17.5 percent). About one in eight (12.2 percent) indicated that LSD would be easily available, and 10.7 percent reported easy availability for heroin. Between 2002 and 2011, there were declines in the perceived availability for all four drugs.
- A majority of youths aged 12 to 17 (89.3 percent) in 2011 reported that their parents would strongly disapprove of their trying marijuana once or twice. Current marijuana use was much less prevalent among youths who perceived strong parental disapproval for trying marijuana once or twice than for those who did not (5.0 vs. 31.5 percent).
- In 2011, 75.1 percent of youths aged 12 to 17 reported having seen or heard drug or alcohol prevention messages from sources outside of school, which was lower than in 2002 (83.2 percent). The percentage of school-enrolled youths reporting that they had seen or heard prevention messages at school also declined during this period, from 78.8 to 74.6 percent.

Substance Dependence, Abuse, and Treatment

- In 2011, an estimated 20.6 million persons (8.0 percent of the population aged 12 or older) were classified with substance dependence or abuse in the past year based on criteria specified in the *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition (DSM-IV). Of these, 2.6 million were classified with dependence or abuse of both alcohol and illicit drugs, 3.9 million had dependence or abuse of illicit drugs but not alcohol, and 14.1 million had dependence or abuse of alcohol but not illicit drugs.
- Between 2002 and 2010, the number of persons with substance dependence or abuse was stable, ranging from 21.6 million to 22.7 million. However, the number in 2011 (20.6 million) was lower than the number in 2010 (22.2 million).
- The specific illicit drugs that had the highest levels of past year dependence or abuse in 2011 were marijuana (4.2 million), pain relievers (1.8 million), and cocaine (0.8 million). The number of persons with marijuana dependence or abuse did not change between 2002 and 2011. Between 2004 and 2011, the number with pain reliever dependence or abuse increased from 1.4 million to 1.8 million, and between 2006 and 2011, the number with cocaine dependence or abuse declined from 1.7 million to 0.8 million.
- The number of persons with heroin dependence or abuse increased from 214,000 in 2007 to 426,000 in 2011.
- In 2011, adults aged 21 or older who had first used alcohol at age 14 or younger were more than 7 times as likely to be classified with alcohol dependence or abuse than adults who had their first drink at age 21 or older (13.8 vs. 1.8 percent).
- Between 2002 and 2011, the percentage of youths aged 12 to 17 with substance dependence or abuse declined from 8.9 to 6.9 percent.
- Treatment need is defined as having substance dependence or abuse or receiving treatment at a specialty facility (hospital inpatient, drug or alcohol rehabilitation, or mental health centers) within the past 12 months. In 2011, 21.6 million persons aged 12 or older needed treatment for an illicit drug or alcohol use problem (8.4 percent of persons aged 12 or older). Of these, 2.3 million (0.9 percent of persons aged 12 or older and 10.8 percent of those who needed treatment) received treatment at a specialty facility. Thus, 19.3 million persons (7.5 percent of the population aged 12 or older) needed treatment for an illicit drug or alcohol use problem but did not receive treatment at a specialty facility in the past year.
- Of the 19.3 million persons aged 12 or older in 2011 who were classified as needing substance use treatment but did not receive treatment at a specialty facility in the past year, 912,000 persons (4.7 percent) reported that they felt they needed treatment for their illicit drug or alcohol use problem. Of these 912,000 persons who felt they needed treatment, 281,000 (30.8 percent) reported that they made an effort to get treatment, and 631,000 (69.2 percent) reported making no effort to get treatment.
- The number of people receiving specialty substance abuse treatment in the past year in 2011 (2.3 million) was similar to the number in 2002 (2.3 million). However, the number receiving specialty treatment for a problem with nonmedical pain reliever use increased during this period, from 199,000 to 438,000.

1. Introduction

This report presents a first look at results from the 2011 National Survey on Drug Use and Health (NSDUH), an annual survey of the civilian, noninstitutionalized population of the United States aged 12 years old or older. The report presents national estimates of rates of use, numbers of users, and other measures related to illicit drugs, alcohol, and tobacco products. The report focuses on trends between 2010 and 2011 and from 2002 to 2011, as well as differences across population subgroups in 2011. NSDUH estimates related to mental health, which were included in national findings reports prior to 2009, are not included in this 2011 report.

Summary of NSDUH

NSDUH is the primary source of statistical information on the use of illegal drugs, alcohol, and tobacco by the U.S. civilian, noninstitutionalized population aged 12 or older. Conducted by the Federal Government since 1971, the survey collects data through face-to-face interviews with a representative sample of the population at the respondent's place of residence. The survey is sponsored by the Substance Abuse and Mental Health Services Administration (SAMHSA), U.S. Department of Health and Human Services, and is planned and managed by SAMHSA's Center for Behavioral Health Statistics and Quality (CBHSQ). Data collection and analysis are conducted under contract with RTI International.¹ This section briefly describes the survey methodology; a more complete description is provided in Appendix A.

NSDUH collects information from residents of households and noninstitutional group quarters (e.g., shelters, rooming houses, dormitories) and from civilians living on military bases. The survey excludes homeless persons who do not use shelters, military personnel on active duty, and residents of institutional group quarters, such as jails and hospitals. Appendix C describes substance use surveys that cover populations outside the NSDUH target population.

From 1971 through 1998, the survey employed paper and pencil data collection. Since 1999, the NSDUH interview has been carried out using computer-assisted interviewing (CAI). Most of the questions are administered with audio computer-assisted self-interviewing (ACASI). ACASI is designed to provide the respondent with a highly private and confidential mode for responding to questions in order to increase the level of honest reporting of illicit drug use and other sensitive behaviors. Less sensitive items are administered by interviewers using computer-assisted personal interviewing.

The 2011 NSDUH continued to employ a State-based design with an independent, multistage area probability sample within each State and the District of Columbia. The eight States with the largest population (which together account for about half of the total U.S. population aged 12 or older) are designated as large sample States (California, Florida, Illinois, Michigan, New York, Ohio, Pennsylvania, and Texas) and have a sample size of about 3,600 each. For the remaining 42 States and the District of Columbia, the sample size is about 900 per State. In 2011, four States in the Gulf Coast (Alabama, Florida, Louisiana, and Mississippi) had a

¹ RTI International is a trade name of Research Triangle Institute.

1-year supplemental sample to facilitate a study of the impact of the April 2010 Deepwater Horizon oil spill on substance use and mental health. In all States and the District of Columbia, the design oversampled youths and young adults; each State's sample was approximately equally distributed among three age groups: 12 to 17 years, 18 to 25 years, and 26 years or older.

Nationally, screening was completed at 156,048 addresses, and 70,109 completed interviews were obtained, which reflect the oversample of about 2,000 cases in the Gulf Coast. The survey was conducted from January through December 2011. Weighted response rates for household screening and for interviewing were 87.0 and 74.4 percent, respectively. See Appendix B for more information on NSDUH response rates.

Limitations on Trend Measurement

Trend analysis using NSDUH data is limited to 2002 to 2011, even though the survey has been conducted since 1971. Because of the shift in interviewing method in 1999, the estimates from the pre-1999 surveys are not comparable with estimates from the current CAI-based surveys. Although the design of the 2002 through 2011 NSDUHs is similar to the design of the 1999 through 2001 surveys, methodological differences affect the comparability of the 2002 to 2011 estimates with estimates from prior surveys. The most important change was the addition of a \$30 incentive payment in 2002. Also, the name of the survey was changed in 2002, from the National Household Survey on Drug Abuse (NHSDA) to the current name. Improved data collection quality control procedures were introduced in the survey starting in 2001, and updated population data from the 2000 decennial census were incorporated into the sample weights starting with the 2002 estimates. Analyses of the effects of these factors on NSDUH estimates have shown that 2002 and later data should not be compared with 2001 and earlier data from the survey series to assess changes over time. Appendix C of the 2004 NSDUH report on national findings discusses this in more detail (Office of Applied Studies, 2005).

Because of changes in the questionnaire, estimates for methamphetamine, stimulants, and psychotherapeutics in this report should not be compared with corresponding estimates presented in previous reports for data years prior to 2007. Estimates for 2002 to 2006 for these drug categories in this report, as well as in the 2007 and 2008 reports, incorporate statistical adjustments that enable year-to-year comparisons to be made over the period from 2002 to 2011.

The calculation of NSDUH person-level weights includes a calibration step that results in weights that are consistent with population control totals obtained from the U.S. Census Bureau (see Section A.3.3 in Appendix A). These control totals are based on the most recently available decennial census; the Census Bureau updates these control totals annually to account for population changes after the census. For the analysis weights in the 2002 through 2010 NSDUHs, the control totals were derived from the 2000 census data; for the 2011 NSDUH weights, the control totals were based on data from the 2010 census. This shift to the 2010 census data could affect comparisons between substance use estimates in 2011 and those from prior years. Analyses of the impact of this change in NSDUH weights show that estimates of the number of substance users for some demographic groups were substantially affected, but percentages of substance users within these groups (i.e., rates) were not. Section B.4.3 in Appendix B provides results of investigations of the change to use of 2010 census control totals for the 2011 NSDUH.

Format of Report and Data Presentation

This report has separate chapters that discuss findings on the use of illicit drugs; use of alcohol; use of tobacco products; initiation of substance use; prevention-related issues; and substance dependence, abuse, and treatment. A final chapter summarizes the results and discusses key findings on marijuana and heroin use and the nonmedical use of prescription drugs, including comparisons with other survey results. The data and findings described in this report are based on a comprehensive set of tables, referred to as "detailed tables," that include population estimates (e.g., numbers of drug users), rates (e.g., percentages of the population using drugs), and standard errors of estimates. These tables are available separately on the SAMHSA Web site (<http://www.samhsa.gov/data/>). In addition, the tables are accompanied by a glossary that covers key definitions used in this report and in the detailed tables. Appendices in this report describe the survey (Appendix A), technical details on the statistical methods and measurement (Appendix B), and other sources of related data (Appendix C). A list of references cited in the report (Appendix D) and contributors to this report (Appendix E) also are provided.

Text, figures, and detailed tables present prevalence measures for the population in terms of both the number of persons and the percentage of the population and by lifetime (i.e., ever used), past year, and past month use. Analyses focus primarily on past month use, also referred to as "current use." Where applicable, footnotes are included in tables and figures to indicate whether the 2011 estimates are significantly different from 2010 or earlier estimates. In addition, some estimates are presented based on data combined from two or more survey years to increase precision of the estimates; those estimates are annual averages based on multiple years of data.

During regular data collection and processing checks for the 2011 NSDUH, data errors were identified. These errors affected the data for Pennsylvania (2006 to 2010) and Maryland (2008 and 2009). Data and estimates for 2011 were not affected. The errors had minimal impact on the national estimates. The only estimates appreciably affected in the report and detailed tables are estimates for the mid-Atlantic division and the Northeast region. Cases with erroneous data were removed from data files, and the remaining cases were reweighted to provide representative estimates. Therefore, some estimates for 2010 and other prior years in the 2011 national findings report and the 2011 detailed tables will differ from corresponding estimates found in some previous reports and tables. Further information is available in Section B.3.5 in Appendix B of this report.

All estimates presented in the report have met the criteria for statistical reliability (see Section B.2.2 in Appendix B). Estimates that do not meet these criteria are suppressed and do not appear in tables, figures, or text. Statistical tests have been conducted for all statements appearing in the text of the report that compare estimates between years or subgroups of the population. Suppressed estimates are not included in statistical tests of comparisons. For example, a statement that "whites had the highest prevalence" means that the rate among whites was higher than the rate among all nonsuppressed racial/ethnic subgroups, but not necessarily higher than the rate among a subgroup for which the estimate was suppressed. Unless explicitly stated that a difference is not statistically significant, all statements that describe differences are significant at the .05 level. Statistically significant differences are described using terms such as "higher," "lower," "increased," and "decreased." Statements that use terms such as "similar," "no difference," "same," or "remained steady" to describe the relationship between estimates denote

that a difference is not statistically significant. When a set of estimates for survey years or population subgroups is presented without a statement of comparison, statistically significant differences among these estimates are not implied and testing may not have been conducted.

Data are presented for racial/ethnic groups based on guidelines for collecting and reporting race and ethnicity data (Office of Management and Budget [OMB], 1997). Because respondents could choose more than one racial group, a "two or more races" category is included for persons who reported more than one category (i.e., white, black or African American, American Indian or Alaska Native, Native Hawaiian, Other Pacific Islander, Asian, Other). Respondents choosing both Native Hawaiian and Other Pacific Islander but no other categories are classified as being in the "Native Hawaiian or Other Pacific Islander" category instead of the "two or more race" category. Except for the "Hispanic or Latino" group, the racial/ethnic groups include only non-Hispanics. The category "Hispanic or Latino" includes Hispanics of any race.

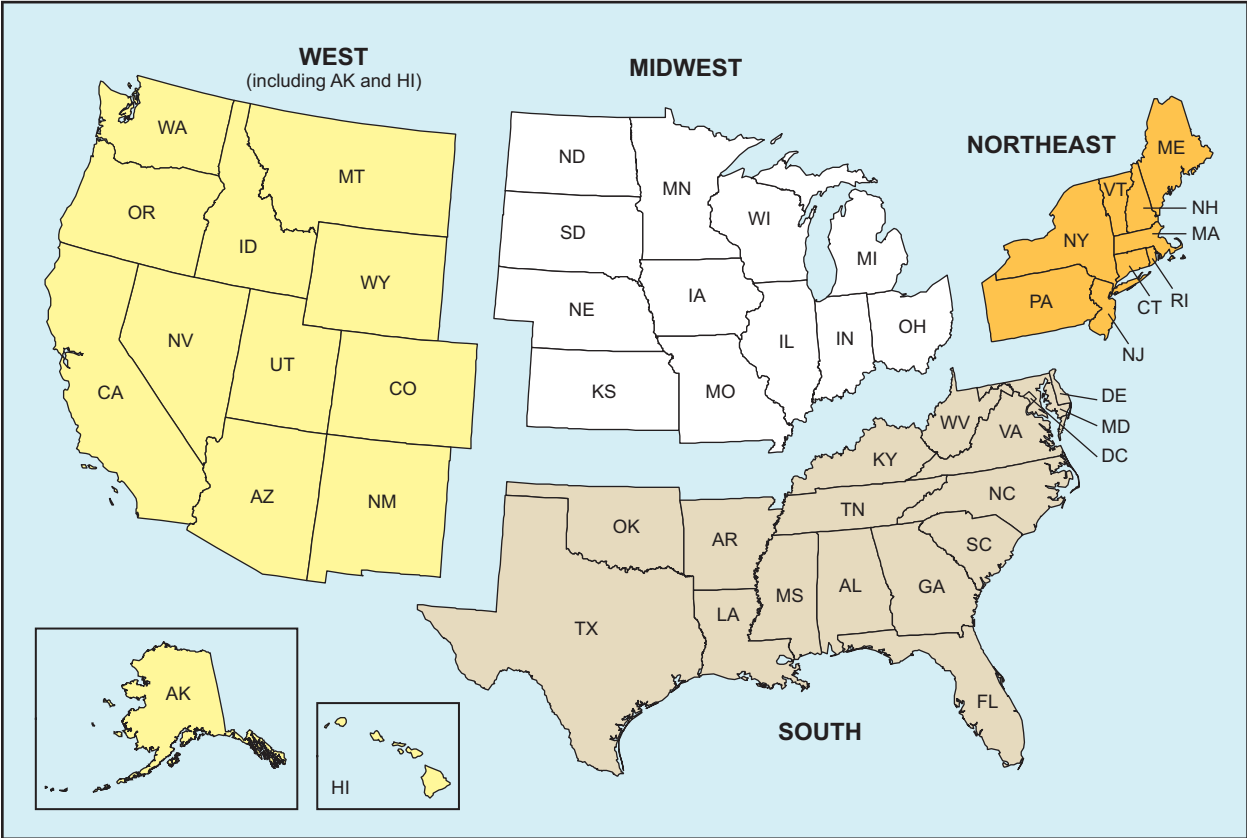

Data in this report also are presented for four U.S. geographic regions as defined by the U.S. Census Bureau (Figure 1.1). Other geographic comparisons also are made based on county type, a variable that reflects different levels of urbanicity and metropolitan area inclusion of counties. This county classification was originally developed and subsequently updated by the U.S. Department of Agriculture (Butler & Beale, 1994). Each county is either inside or outside a metropolitan statistical area (MSA), based on metropolitan area definitions issued by the OMB in June 2003 (OMB, 2003). Large metropolitan areas have a population of 1 million or more. Small metropolitan areas have a population of fewer than 1 million. Nonmetropolitan areas are outside of MSAs. Counties in nonmetropolitan areas are further classified based on the number of people in the county who live in an urbanized area, as defined by the Census Bureau at the subcounty level. "Urbanized" counties have a population of 20,000 or more in urbanized areas, "less urbanized" counties have at least 2,500 but fewer than 20,000 population in urbanized areas, and "completely rural" counties have populations of fewer than 2,500 in urbanized areas.

Other NSDUH Reports and Data

Other reports focusing on specific topics of interest will be produced using the 2011 NSDUH data and made available on SAMHSA's Web site. In particular, data on mental health will be discussed in a separate report to be released later this year: *Results from the 2011 National Survey on Drug Use and Health: Mental Health Findings*. State-level estimates for substance use and mental health for 2010-2011 are scheduled to be released by early 2013.

The detailed tables, other descriptive reports and in-depth analytic reports focusing on specific issues or populations, and methodological information on NSDUH are all available at <http://www.samhsa.gov/data/>. In addition, CBHSQ makes public use data files available through the Substance Abuse and Mental Health Data Archive at <http://www.datafiles.samhsa.gov>. Currently, files are available from the 1979 to 2010 surveys. The 2011 NSDUH public use file will be available by the end of 2012.

Figure 1.1 U.S. Census Bureau Regions

2. Illicit Drug Use

The National Survey on Drug Use and Health (NSDUH) obtains information on nine categories of illicit drug use: use of marijuana, cocaine, heroin, hallucinogens, and inhalants, as well as the nonmedical use of prescription-type pain relievers, tranquilizers, stimulants, and sedatives. In these categories, hashish is included with marijuana, and crack is considered a form of cocaine. Several drugs are grouped under the hallucinogens category, including LSD, PCP, peyote, mescaline, psilocybin mushrooms, and "Ecstasy" (MDMA). Inhalants include a variety of substances, such as nitrous oxide, amyl nitrite, cleaning fluids, gasoline, spray paint, other aerosol sprays, and glue. Respondents are asked to report use of inhalants to get high but not to report times when they accidentally inhaled a substance.

The four categories of prescription-type drugs (pain relievers, tranquilizers, stimulants, and sedatives) cover numerous medications that currently are or have been available by prescription. They also include drugs within these groupings that originally were prescription medications but currently may be manufactured and distributed illegally, such as methamphetamine, which is included under stimulants. Respondents are asked to report only "nonmedical" use of these drugs, defined as use without a prescription of the individual's own or simply for the experience or feeling the drugs caused. Use of over-the-counter drugs and legitimate use of prescription drugs are not included. NSDUH reports combine the four prescription-type drug groups into a category referred to as "psychotherapeutics."

Estimates of "illicit drug use" reported from NSDUH reflect the use of any of the nine drug categories listed above. Use of alcohol and tobacco products, while illegal for youths, is not included in these estimates, but is discussed in Chapters 3 and 4.

- In 2011, an estimated 22.5 million Americans aged 12 or older were current (past month) illicit drug users, meaning they had used an illicit drug during the month prior to the survey interview (Figure 2.1). This estimate represents 8.7 percent of the population aged 12 or older.
- The overall rate of current illicit drug use among persons aged 12 or older in 2011 (8.7 percent) was similar to the rates in 2010 (8.9 percent), 2009 (8.7 percent), and 2002 (8.3 percent), but it was higher than the rates in most years from 2003 through 2008 (Figure 2.2).
- In 2011, marijuana was the most commonly used illicit drug, with 18.1 million current users. It was used by 80.5 percent of current illicit drug users. About two thirds (64.3 percent) of illicit drug users used only marijuana in the past month. Also, in 2011, 8.0 million persons aged 12 or older were current users of illicit drugs other than marijuana (or 35.7 percent of illicit drug users aged 12 or older). Current use of other drugs but not marijuana was reported by 19.5 percent of illicit drug users, and 16.2 percent of illicit drug users reported using both marijuana and other drugs.

Figure 2.1 Past Month Illicit Drug Use among Persons Aged 12 or Older: 2011

¹ Illicit Drugs include marijuana/hashish, cocaine (including crack), heroin, hallucinogens, inhalants, or prescription-type psychotherapeutics used nonmedically.

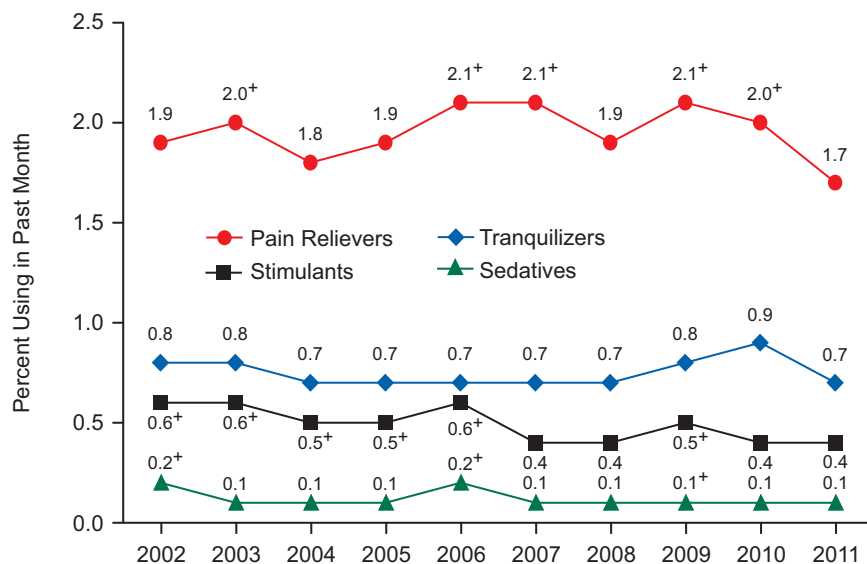

- The number and percentage of persons aged 12 or older who were current users of marijuana in 2011 (18.1 million or 7.0 percent) were similar to the estimates for 2010 (17.4 million or 6.9 percent). The 2011 rate of current marijuana use also was similar to the rate in 2009 (6.7 percent), but it was higher than those in 2002 through 2008. Between 2007 and 2011, for example, the rate of use increased from 5.8 to 7.0 percent, and the number of users increased from 14.5 million to 18.1 million.
- An estimated 8.0 million people aged 12 or older (3.1 percent) were current users of illicit drugs other than marijuana in 2011. The majority of these users (6.1 million persons or 2.4 percent of the population) were nonmedical users of psychotherapeutic drugs, including 4.5 million users of pain relievers, 1.8 million users of tranquilizers, 970,000 users of stimulants, and 231,000 users of sedatives.
- The number and percentage of persons aged 12 or older who were current nonmedical users of psychotherapeutic drugs in 2011 (6.1 million or 2.4 percent) were lower than those in 2010 (7.0 million or 2.7 percent) and 2009 (7.0 million or 2.8 percent) (Figure 2.2).
- The number and percentage of persons aged 12 or older who were current nonmedical users of pain relievers in 2011 (4.5 million or 1.7 percent) were lower than those in 2010 (5.1 million or 2.0 percent) and 2009 (5.3 million or 2.1 percent) (Figure 2.3).

Figure 2.2 Past Month Use of Selected Illicit Drugs among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Figure 2.3 Past Month Nonmedical Use of Types of Psychotherapeutic Drugs among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- The number and percentage of persons aged 12 or older who were current nonmedical users of stimulants in 2011 (970,000 or 0.4 percent) were similar to those in 2010 (1.1 million or 0.4 percent), but lower than those in 2009 (1.3 million or 0.5 percent).
- The number and percentage of persons aged 12 or older who were current users of methamphetamine in 2011 (439,000 or 0.2 percent) were similar to those from 2007 through 2010, but lower than those from 2002 through 2006. The previous numbers and percentages were 353,000 (0.1 percent) in 2010, 502,000 (0.2 percent) in 2009, 314,000 (0.1 percent) in 2008, 530,000 (0.2 percent) in 2007, 731,000 (0.3 percent) in 2006, 628,000 (0.3 percent) in 2005, 706,000 (0.3 percent) in 2004, 726,000 (0.3 percent) in 2003, and 683,000 (0.3 percent) in 2002.
- The number and percentage of persons aged 12 or older who were current users of cocaine in 2011 (1.4 million or 0.5 percent) were similar to those in 2010 (1.5 million or 0.6 percent) and 2009 (1.6 million or 0.7 percent), but lower than those from 2002 through 2008 (Figure 2.2). The previous numbers and percentages were 1.9 million (0.7 percent) in 2008, 2.1 million (0.8 percent) in 2007, 2.4 million (1.0 percent) in 2006, 2.4 million (1.0 percent) in 2005, 2.0 million (0.8 percent) in 2004, 2.3 million (1.0 percent) in 2003, and 2.0 million (0.9 percent) in 2002.
- The number and percentage of persons aged 12 or older who were current heroin users in 2011 (281,000 or 0.1 percent) were similar to those from 2006 through 2010 (239,000 or 0.1 percent in 2010; 193,000 or 0.1 percent in 2009; 213,000 or 0.1 percent in 2008; 161,000 or 0.1 percent in 2007; and 339,000 or 0.1 percent in 2006), but were higher than those in 2005 (136,000 or 0.1 percent) and 2003 (119,000 or 0.1 percent) (Figure 2.4). Additionally, the number and percentage of persons aged 12 or older who were past year heroin users in 2011 (620,000 or 0.2 percent) were similar to those in 2008 to 2010 (621,000 or 0.2 percent in 2010; 582,000 or 0.2 percent in 2009; and 455,000 or 0.2 percent in 2008) and in 2006 (560,000 or 0.2 percent), but were higher than those from 2003 through 2005 and in 2007.
- The number and percentage of persons aged 12 or older who were current users of hallucinogens in 2011 (972,000 or 0.4 percent) were lower than those in 2010 (1.2 million or 0.5 percent), 2009 (1.3 million or 0.5 percent), and 2002 (1.2 million or 0.5 percent) (Figure 2.2).

Age

- The rate of current illicit drug use varied by age. Among youths aged 12 to 17 in 2011, the rate increased from 3.3 percent at ages 12 or 13 to 9.2 percent at ages 14 or 15 to 17.2 percent at ages 16 or 17 (Figure 2.5). The highest rate of current illicit drug use was among 18 to 20 year olds (23.8 percent), with the next highest rate among 21 to 25 year olds (19.9 percent). Thereafter, the rate generally declined with age, although not all declines were significant.

Figure 2.4 Past Month and Past Year Heroin Use among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Figure 2.5 Past Month Illicit Drug Use among Persons Aged 12 or Older, by Age: 2010 and 2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- In 2011, adults aged 26 or older were less likely to be current users of illicit drugs than youths aged 12 to 17 or young adults aged 18 to 25 (6.3 vs. 10.1 and 21.4 percent, respectively) (Figure 2.6). However, there were more current users of illicit drugs aged 26 or older (12.6 million) than users aged 12 to 17 (2.5 million) and users aged 18 to 25 (7.4 million) combined.

Figure 2.6 Past Month Illicit Drug Use among Persons Aged 12 or Older, by Age: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Youths Aged 12 to 17

- The rate of current illicit drug use among youths aged 12 to 17 remained unchanged between 2009 and 2011 (10.1 percent in each year), but it was higher than the rate in 2008 (9.3 percent). Between 2002 and 2008, the rate declined from 11.6 to 9.3 percent (Figure 2.7).
- In 2011, 10.1 percent of youths aged 12 to 17 were current illicit drug users, with 7.9 percent current users of marijuana, 2.8 percent current nonmedical users of psychotherapeutic drugs, 0.9 percent current users of hallucinogens, 0.9 percent current users of inhalants, and 0.3 percent current users of cocaine.

Figure 2.7 Past Month Use of Selected Illicit Drugs among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- Among youths aged 12 to 17, the specific illicit drugs used in the past month varied by age in 2011. Among 12 or 13 year olds, 1.3 percent used marijuana and 1.3 percent used psychotherapeutic drugs nonmedically (which was a decrease from 2.0 percent in 2010, with most of the decrease occurring in the nonmedical use of pain relievers from 1.8 percent in 2010 to 1.1 percent in 2011). Among 14 or 15 year olds, 6.7 percent used marijuana, 2.6 percent used psychotherapeutic drugs nonmedically, and 0.8 percent used hallucinogens. Among 16 or 17 year olds, 15.1 percent used marijuana, 4.2 percent used psychotherapeutic drugs nonmedically, 1.6 percent used hallucinogens, and 0.5 percent used cocaine. Rates of current use of inhalants were 1.0 percent for 12 or 13 year olds, 0.9 percent for 14 or 15 year olds, and 0.7 percent for 16 to 17 year olds.
- After gradually declining from 11.6 percent in 2002 to 9.3 percent in 2008, the rate of current illicit drug use among 12 to 17 year olds increased to 10.1 percent in 2009, 2010, and 2011 (Figure 2.7). Current marijuana use declined from 8.2 percent in 2002 to 6.7 percent in 2008 before increasing to 7.4 percent in 2009 and 2010; the prevalence of current marijuana use in 2011 (7.9 percent) also was greater than that in 2008, but it was similar to the rates in 2009 and 2010. Current nonmedical use of psychotherapeutic drugs declined from 4.0 percent in 2002 and 2003 to 2.8 percent in 2011. This includes the decrease in the current nonmedical use of pain relievers from 3.2 percent in 2002 to 2.3 percent in 2011.

Young Adults Aged 18 to 25

- In 2011, the rate of current illicit drug use was higher among young adults aged 18 to 25 (21.4 percent) than among youths aged 12 to 17 (10.1 percent) and adults aged 26 or older (6.3 percent). Among young adults, the 2011 rate was similar to the 2009 (21.4 percent) and 2010 (21.6 percent) rates, but it was higher than the 2008 rate (19.7 percent) (Figure 2.8).

Figure 2.8 Past Month Use of Selected Illicit Drugs among Young Adults Aged 18 to 25: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- Among young adults, the 2011 rate of current marijuana use (19.0 percent) was similar to the 2009 (18.2 percent) and 2010 (18.5 percent) rates, but it was higher than the 2008 rate (16.6 percent).
- In 2011, the rate of current nonmedical use of psychotherapeutic drugs among young adults aged 18 to 25 was 5.0 percent, which was lower than the rates from 2003 through 2010. Similarly, in 2011, the rate of current nonmedical use of pain relievers was 3.6 percent, which was lower than the rates from 2002 through 2010. Rates of current nonmedical use of pain relievers among young adults for 2002 to 2010 ranged from 4.1 percent in 2002 to 5.0 percent in 2006; the rate in 2010 was 4.4 percent.

- In 2011, the rate of current use of cocaine among young adults aged 18 to 25 was 1.4 percent, which was similar to the rates from 2008 through 2010, but was lower than the rates from 2002 through 2007.

Adults Aged 26 or Older

- In 2011, the rate of current illicit drug use among adults aged 26 or older was 6.3 percent, with 4.8 percent current users of marijuana and 1.9 percent current nonmedical users of psychotherapeutic drugs. Less than 1 percent each were current users of cocaine (0.4 percent), heroin (0.1 percent), and inhalants (0.1 percent). These rates were similar to those in 2009 and 2010. For example, 6.3 percent of adults aged 26 or older in 2009 and 6.6 percent of those in 2010 were current illicit drug users.
- Among adults aged 50 to 59, the rate of current illicit drug use increased from 2.7 to 6.3 percent between 2002 and 2011 (Figure 2.9). For those aged 50 to 54, the rate increased from 3.4 percent in 2002 to 6.7 percent in 2011. Among those aged 55 to 59, current illicit drug use increased from 1.9 percent in 2002 to 6.0 percent in 2011. These patterns and trends partially reflect the aging into these age groups of members of the baby boom cohort, whose rates of illicit drug use have been higher than those of older cohorts. The baby boom cohort refers to persons born in the United States after World War II between 1946 and 1964 (Han, Gfroerer, & Colliver, 2009).

Gender

- In 2011, as in prior years, the rate of current illicit drug use among persons aged 12 or older was higher for males (11.1 percent) than for females (6.5 percent). Males were more likely than females to be current users of several different illicit drugs, including marijuana (9.3 vs. 4.9 percent), nonmedical use of prescription drugs (2.6 vs. 2.2 percent), cocaine (0.7 vs. 0.4 percent), and hallucinogens (0.5 vs. 0.3 percent). The 2011 rates for both males and females aged 12 or older were similar to those reported in 2010, with the exception of a decrease in the current nonmedical use of prescription drugs among females (down from 2.5 percent in 2010).
- In 2011, the rate of current illicit drug use was higher among males aged 12 to 17 than females aged 12 to 17 (10.8 vs. 9.3 percent), which represents a change from 2010, when current illicit drug use did not differ significantly between males and females (10.4 and 9.8 percent). Males aged 12 to 17 also were more likely than females to be current marijuana users (9.0 vs. 6.7 percent). However, females aged 12 to 17 were more likely than males to be current nonmedical users of psychotherapeutic drugs (3.2 vs. 2.4 percent) and current nonmedical users of pain relievers (2.6 vs. 1.9 percent).
- The rate of current marijuana use among males aged 12 to 17 declined from 9.1 percent in 2002 to 6.9 percent in 2006, then increased between 2006 and 2009 (8.4 percent); rates remained stable after 2009 (8.4 percent in 2010 and 9.0 percent in 2011) (Figure 2.10). Among females aged 12 to 17, the rate of current marijuana use changed little between 2002 (7.2 percent) and 2004 (7.1 percent), then declined to 5.8 percent in 2007 before increasing in 2011 to 6.7 percent.

Figure 2.9 Past Month Illicit Drug Use among Adults Aged 50 to 59: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Figure 2.10 Past Month Marijuana Use among Youths Aged 12 to 17, by Gender: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Pregnant Women

- Among pregnant women aged 15 to 44, 5.0 percent were current illicit drug users based on data averaged across 2010 and 2011. This was lower than the rate among women in this age group who were not pregnant (10.8 percent). Among pregnant women aged 15 to 44, the average rate of current illicit drug use in 2010-2011 (5.0 percent) was not significantly different from the rate averaged across 2008-2009 (4.5 percent).
- The rate of current illicit drug use in the combined 2010-2011 data was 20.9 percent among pregnant women aged 15 to 17, 8.2 percent among pregnant women aged 18 to 25, and 2.2 percent among pregnant women aged 26 to 44. None of these rates were significantly different from those in the combined 2008-2009 data (15.8 percent among pregnant women aged 15 to 17, 7.1 percent among pregnant women aged 18 to 25, and 2.3 percent among pregnant women aged 26 to 44).

Race/Ethnicity

- In 2011, among persons aged 12 or older, the rate of current illicit drug use was lowest among Asians (3.8 percent) (Figure 2.11). The rates were 8.4 percent among Hispanics, 8.7 percent among whites, 10.0 percent among blacks, 11.0 percent among Native Hawaiians or Other Pacific Islanders, 13.4 percent among American Indians or Alaska Natives, and 13.5 percent among persons of two or more races.
- There were no statistically significant differences in the rates of current illicit drug use between 2010 and 2011 or between 2002 and 2011 for any of the racial/ethnic groups, except for Hispanics. The current illicit drug use rate for Hispanics increased between 2002 and 2011 (from 7.2 to 8.4 percent).

Education

- Illicit drug use in 2011 varied by the educational status of adults aged 18 or older, with the rate of current illicit drug use lower among college graduates (5.4 percent) than those with some college education (10.4 percent), high school graduates (8.9 percent), and those who had not graduated from high school (11.1 percent).

College Students

- In 2011, the rate of current use of illicit drugs was 22.0 percent among full-time college students aged 18 to 22. This was similar to the rate among other persons aged 18 to 22 (23.4 percent), which included part-time college students, students in other grades or types of institutions, and nonstudents.

Figure 2.11 Past Month Illicit Drug Use among Persons Aged 12 or Older, by Race/Ethnicity: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

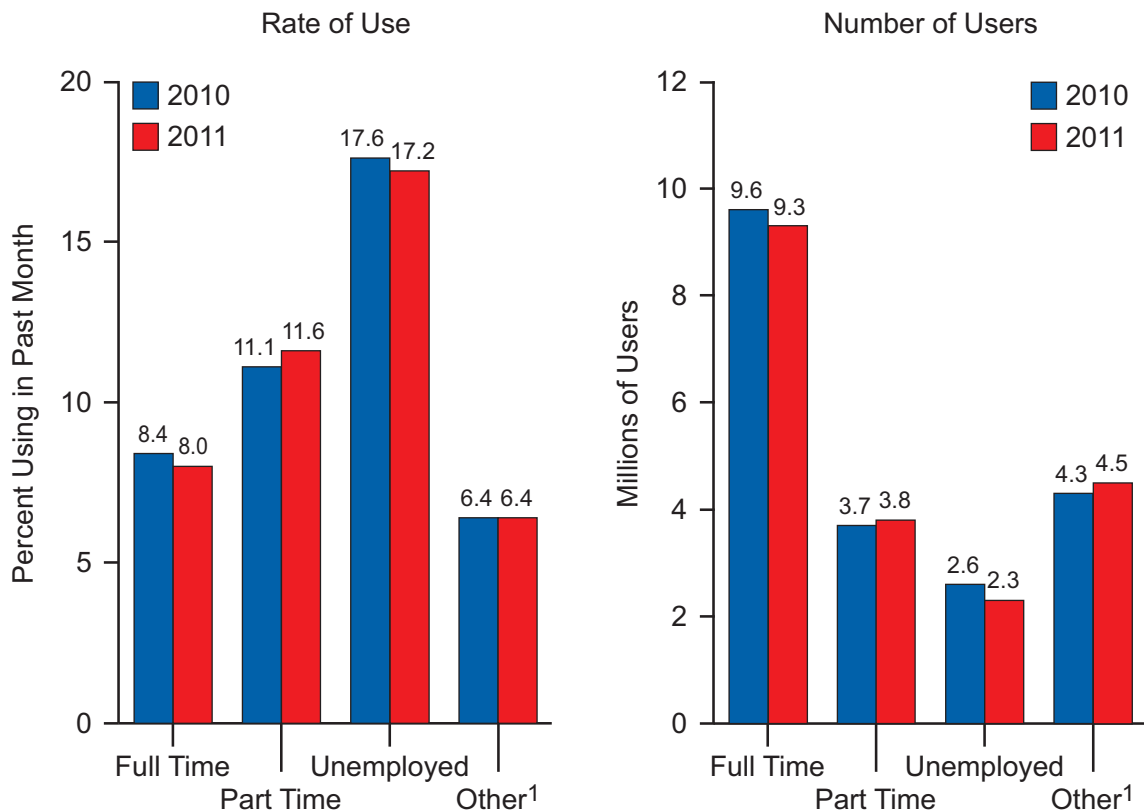

Note: Sample sizes for American Indians or Alaska Natives and for persons of two or more races were too small for reliable trend presentation for these groups. Due to low precision, estimates for Native Hawaiians or Other Pacific Islanders are not shown.

- In 2011, the rate of current illicit drug use was 25.8 percent among male full-time college students aged 18 to 22, which was higher than the rate among female full-time college students aged 18 to 22 (18.9 percent). Similarly, 23.7 percent of male full-time college students aged 18 to 22 were current marijuana users compared with 17.5 percent of female full-time college students aged 18 to 22.

Employment

- Current illicit drug use differed by employment status in 2011. Among adults aged 18 or older, the rate of current illicit drug use was higher for those who were unemployed (17.2 percent) than for those who were employed full time (8.0 percent), employed part time (11.6 percent), or "other" (6.4 percent) (which includes students, persons keeping house or caring for children full time, retired or disabled persons, or other persons not in the labor force) (Figure 2.12).

Figure 2.12 Past Month Illicit Drug Use among Persons Aged 18 or Older, by Employment Status: 2010 and 2011

[†]Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

¹The Other Employment category includes students, persons keeping house or caring for children full time, retired or disabled persons, or other persons not in the labor force.

- Although the rate of current illicit drug use was higher among unemployed persons in 2011 compared with those who were either employed full time, employed part time, or "other," most of these users were employed. Of the 19.9 million current illicit drug users aged 18 or older in 2011, 13.1 million (65.7 percent) were employed either full or part time.

Geographic Area

- Among persons aged 12 or older, the rate of current illicit drug use in 2011 was 10.5 percent in the West, 9.2 percent in the Northeast, 8.5 percent in the Midwest, and 7.5 percent in the South.
- In 2011, the rate of current illicit drug use among persons aged 12 or older was 9.2 percent in large metropolitan counties, 8.7 percent in small metropolitan counties, and 7.2 percent in nonmetropolitan counties as a group (Figure 2.13). Within nonmetropolitan areas, the rate was 8.5 percent in urbanized counties, 6.3 percent in less urbanized counties, and 5.7 percent in completely rural counties.

Figure 2.13 Past Month Illicit Drug Use among Persons Aged 12 or Older, by County Type: 2011

Criminal Justice Populations

- In 2011, an estimated 1.7 million adults aged 18 or older were on parole or other supervised release from prison at some time during the past year. More than one quarter of these (26.5 percent) were current illicit drug users, with 20.4 percent reporting current use of marijuana and 9.1 percent reporting current nonmedical use of psychotherapeutic drugs. These rates were higher than those reported by adults aged 18 or older who were not on parole or supervised release during the past year (8.4 percent for illicit drug use, 6.8 percent for marijuana use, and 2.3 percent for nonmedical use of psychotherapeutic drugs).
- In 2011, an estimated 4.7 million adults aged 18 or older were on probation at some time during the past year. More than one quarter (28.5 percent) were current illicit drug users, with 23.6 percent reporting current use of marijuana and 10.1 percent reporting current nonmedical use of psychotherapeutic drugs. These rates were higher than those reported by adults who were not on probation during the past year (8.2 percent for illicit drug use, 6.6 percent for marijuana use, and 2.2 percent for nonmedical use of psychotherapeutic drugs).

Frequency of Marijuana Use

- In 2011, an estimated 16.7 percent of past year marijuana users aged 12 or older used marijuana on 300 or more days within the past 12 months. This translates into nearly 5.0 million persons using marijuana on a daily or almost daily basis over a 12-month period.
- In 2011, an estimated 39.1 percent (7.1 million) of current marijuana users aged 12 or older used marijuana on 20 or more days in the past month. This was similar to the 2010 estimate of 39.8 percent or 6.9 million users.

Association with Cigarette and Alcohol Use

- In 2011, the rate of current illicit drug use was approximately 9.5 times higher among youths aged 12 to 17 who smoked cigarettes in the past month (57.6 percent) than it was among those who did not smoke cigarettes in the past month (6.1 percent). Moreover, the 2011 rate of current illicit drug use among youths aged 12 to 17 who smoked cigarettes in the past month was an increase from the 2010 estimate of 52.7 percent.
- In 2011, the rate of current illicit drug use was associated with the level of past month alcohol use. Among youths aged 12 to 17 who were heavy drinkers (i.e., consumed five or more drinks on the same occasion on each of 5 or more days in the past 30 days), 70.4 percent were current illicit drug users, which was higher than the rate among those who were not current alcohol users (5.3 percent). Additionally, among youths aged 12 to 17 who were binge but not heavy drinkers (i.e., consumed five or more drinks on the same occasion on 1 to 4 days in the past 30 days), 44.7 percent were also current illicit drug users.
- In 2011, the rate of current illicit drug use was approximately 17 times higher among youths aged 12 to 17 who both smoked cigarettes and drank alcohol in the past month (68.7 percent) than it was among those who neither smoked cigarettes nor drank alcohol in the past month (4.0 percent).

Driving Under the Influence of Illicit Drugs

- In 2011, 9.4 million persons or 3.7 percent of the population aged 12 or older reported driving under the influence of illicit drugs during the past year. This was a decrease from the rate in 2010 (4.2 percent) and the rate in 2002 (4.7 percent). Across age groups, the rate of driving under the influence of illicit drugs in 2011 was highest among young adults aged 18 to 25 (11.6 percent); this rate for young adults in 2011 was lower than the rate in 2010 (12.7 percent). Additionally, the rate of driving under the influence of illicit drugs during the past year decreased among adults aged 26 or older (from 2.9 percent in 2010 to 2.4 percent in 2011).

Source of Prescription Drugs

- Past year nonmedical users of psychotherapeutic drugs are asked how they obtained the drugs they most recently used nonmedically. Rates averaged across 2010 and 2011 show that over one half of the nonmedical users of pain relievers, tranquilizers, stimulants, and sedatives aged 12 or older got the prescription drugs they most recently used "from a friend or relative for free." About 4 in 5 of these nonmedical users who obtained prescription drugs from a friend or relative for free indicated that their friend or relative had obtained the drugs from one doctor.
- Among persons aged 12 or older in 2010-2011 who used pain relievers nonmedically in the past year, 54.2 percent got the pain relievers they most recently used from a friend or relative for free (Figure 2.14). Another 12.2 percent bought them from a friend or relative (which was higher than the 9.9 percent in 2008-2009). In addition, 4.4 percent of these nonmedical users in 2010-2011 took pain relievers from a friend or relative without asking. More than one in six (18.1 percent) indicated that they got the drugs they most recently used through a prescription from one doctor. Less than 1 in 20 users (3.9 percent) got pain relievers from a drug dealer or other stranger, 1.9 percent got pain relievers from more than one doctor, and 0.3 percent bought them on the Internet. These other percentages were similar to those reported in 2008-2009.
- Among persons aged 12 or older in 2010-2011 who used pain relievers nonmedically in the past year and indicated that they most recently obtained the drugs from a friend or relative for free in the past year, 81.6 percent of the friends or relatives obtained the drugs from just one doctor (Figure 2.14). About 1 in 20 of these past year nonmedical users of pain relievers (5.5 percent) reported that the friend or relative got the pain relievers from another friend or relative for free, 3.9 percent reported that the friend or relative bought the drugs from a friend or relative, 1.9 percent reported that the friend or relative bought the drugs from a drug dealer or other stranger, and 1.8 percent reported that the friend or relative took the drugs from another friend or relative without asking.

Figure 2.14 Source Where Pain Relievers Were Obtained for Most Recent Nonmedical Use among Past Year Users Aged 12 or Older: 2010-2011

Note: The percentages do not add to 100 percent due to rounding.

¹The Other category includes the sources "Wrote Fake Prescription," "Stole from Doctor's Office/Clinic/Hospital/Pharmacy," and "Some Other Way."

3. Alcohol Use

The National Survey on Drug Use and Health (NSDUH) includes questions about the recency and frequency of consumption of alcoholic beverages, such as beer, wine, whiskey, brandy, and mixed drinks. A "drink" is defined as a can or bottle of beer, a glass of wine or a wine cooler, a shot of liquor, or a mixed drink with liquor in it. Times when the respondent only had a sip or two from a drink are not considered to be consumption. For this report, estimates for the prevalence of alcohol use are reported primarily at three levels defined for both males and females and for all ages as follows:

Current (past month) use - At least one drink in the past 30 days.

Binge use - Five or more drinks on the same occasion (i.e., at the same time or within a couple of hours of each other) on at least 1 day in the past 30 days.

Heavy use - Five or more drinks on the same occasion on each of 5 or more days in the past 30 days.

These levels are not mutually exclusive categories of use; heavy use is included in estimates of binge and current use, and binge use is included in estimates of current use.

This chapter is divided into two main sections. Section 3.1 describes trends and patterns of alcohol use among the population aged 12 or older. Section 3.2 is concerned particularly with the use of alcohol by persons aged 12 to 20. These persons are under the legal drinking age in all 50 States and the District of Columbia.

3.1. Alcohol Use among Persons Aged 12 or Older

- Slightly more than half (51.8 percent) of Americans aged 12 or older reported being current drinkers of alcohol in the 2011 survey, similar to the rate in 2010 (51.8 percent). This translates to an estimated 133.4 million current drinkers in 2011.
- Nearly one quarter (22.6 percent) of persons aged 12 or older participated in binge drinking at least once in the 30 days prior to the survey in 2011. This translates to about 58.3 million people. The rate in 2011 was similar to the rate in 2010 (23.1 percent).
- In 2011, heavy drinking was reported by 6.2 percent of the population aged 12 or older, or 15.9 million people. This percentage was lower than the rate of heavy drinking in 2010 (6.7 percent).

Age

- In 2011, rates of current alcohol use were 2.5 percent among persons aged 12 or 13, 11.3 percent of persons aged 14 or 15, 25.3 percent of 16 or 17 year olds, 46.8 percent of those aged 18 to 20, and 69.7 percent of 21 to 25 year olds (Figure 3.1). These estimates were similar to the rates reported in 2010.
- The prevalence of current alcohol use was lower among 60 to 64 year olds (50.9 percent) and adults aged 65 or older (40.3 percent) than among 26 to 29 year olds (65.3 percent).
- Rates of binge alcohol use in 2011 were 1.1 percent among 12 or 13 year olds, 5.7 percent among 14 or 15 year olds, 15.0 percent among 16 or 17 year olds, 31.2 percent among persons aged 18 to 20, and peaked among those aged 21 to 25 at 45.4 percent. The binge drinking rate for 14 or 15 year olds was lower in 2011 than in 2010 (5.7 and 6.7 percent, respectively).

Figure 3.1 Current, Binge, and Heavy Alcohol Use among Persons Aged 12 or Older, by Age: 2011

- The rate of binge drinking in 2011 was 39.8 percent for young adults aged 18 to 25. Heavy alcohol use was reported by 12.1 percent of persons aged 18 to 25, which was lower than the rate in 2010 (13.5 percent).
- The rate of binge drinking among persons aged 65 or older in 2011 was 8.3 percent, while the rate of heavy drinking was 1.7 percent. These rates were similar to the binge and heavy drinking rates in this age group in 2010 (7.6 and 1.6 percent, respectively).
- The rate of current alcohol use among youths aged 12 to 17 was 13.3 percent in 2011. Youth binge and heavy drinking rates were 7.4 and 1.5 percent, respectively. These rates were all similar to those reported in 2010 (13.6, 7.9, and 1.7 percent, respectively).

Gender

- In 2011, an estimated 56.8 percent of males aged 12 or older were current drinkers, which was higher than the rate for females (47.1 percent). However, among youths aged 12 to 17, the percentage of males who were current drinkers (13.3 percent) was similar to the rate for females (13.3 percent).
- Among young adults aged 18 to 25, an estimated 58.1 percent of females and 63.3 percent of males reported current drinking in 2011. The rate for males was lower in 2011 than in 2010 (65.7 percent).

Pregnant Women

- Among pregnant women aged 15 to 44, an estimated 9.4 percent reported current alcohol use, 2.6 percent reported binge drinking, and 0.4 percent reported heavy drinking. These rates were lower than the rates for nonpregnant women in the same age group (55.1, 24.5, and 5.3 percent, respectively). The rate of binge drinking among pregnant women in 2011 and 2010 combined was lower than it was in combined years 2010 and 2009 (2.6 vs. 4.4 percent). All of the estimates by pregnancy status are based on data averaged over 2 years.

Race/Ethnicity

- Among persons aged 12 or older, whites in 2011 were more likely than other racial/ethnic groups to report current use of alcohol (56.8 percent) (Figure 3.2). The rates were 46.9 percent for persons reporting two or more races, 44.7 percent for American Indians or Alaska Natives, 42.5 percent for Hispanics, 42.1 percent for blacks, and 40.0 percent for Asians.
- The rate of binge alcohol use was lowest among Asians (11.6 percent). Rates for other racial/ethnic groups were 18.6 percent for persons reporting two or more races, 19.4 percent for blacks, 23.4 percent for Hispanics, 23.9 percent for whites, and 24.3 percent for American Indians or Alaska Natives.
- Among youths aged 12 to 17 in 2011, Asians had lower rates of current alcohol use than any other racial/ethnic group (7.4 percent), while 10.5 percent of black youths, 12.6 percent of Hispanic youths, 14.6 percent of white youths, 15.2 percent of American Indian or Alaska Native youths, and 17.5 percent of youths reporting two or more races were current drinkers.

Figure 3.2 Current, Binge, and Heavy Alcohol Use among Persons Aged 12 or Older, by Race/Ethnicity: 2011

Note: Due to low precision, estimates for Native Hawaiians or Other Pacific Islanders are not shown.

Education

- Among adults aged 18 or older, the rate of past month alcohol use increased with increasing levels of education. Among adults with less than a high school education, 35.1 percent were current drinkers in 2011, which was lower than the 68.2 percent of college graduates who were current drinkers.
- Among adults aged 18 or older, rates of binge and heavy alcohol use varied by level of education. Among those with some college education, 26.7 percent were binge drinkers, and 7.9 percent were heavy drinkers. Among those who had graduated from college, rates of binge and heavy drinking were 21.8 and 5.4 percent, respectively.

College Students

- Young adults aged 18 to 22 enrolled full time in college were more likely than their peers not enrolled full time (i.e., part-time college students and persons not currently enrolled in college) to use alcohol in the past month, binge drink, and drink heavily. Among full-time college students in 2011, 60.8 percent were current drinkers, 39.1 percent were binge drinkers, and 13.6 percent were heavy drinkers. Among those not enrolled full time in college, these rates were 52.0, 35.4, and 10.5 percent, respectively.
- The pattern of higher rates of current alcohol use, binge alcohol use, and heavy alcohol use among full-time college students compared with rates for others aged 18 to 22 has remained consistent since 2002 (Figure 3.3).
- Among young adults aged 18 to 22, the rate of binge drinking appears to be declining somewhat. In 2002, the binge drinking rate within this age group was 41.0 percent compared with 36.9 percent in 2011. Among full-time college students, the rate decreased from 44.4 to 39.1 percent. Among part-time college students and others not in college, the rate decreased from 38.9 to 35.4 percent during the same time period.

Figure 3.3 Binge Alcohol Use among Adults Aged 18 to 22, by College Enrollment: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Employment

- The rate of current alcohol use was 64.3 percent for full-time employed adults aged 18 or older in 2011, which was higher than the rate for unemployed adults (54.1 percent). However, the rate of binge drinking among unemployed persons (33.2 percent) was higher than among full-time employed persons (29.5 percent).
- Most binge and heavy alcohol users were employed in 2011. Among 56.5 million adult binge drinkers, 42.1 million (74.4 percent) were employed either full or part time. Among 15.5 million heavy drinkers, 11.6 million (74.9 percent) were employed.
- The rate of heavy alcohol use among unemployed adults in 2011 was lower than the rate in 2010 (9.0 vs. 11.1 percent, respectively).

Geographic Area

- The rate of past month alcohol use for people aged 12 or older in 2011 was lower in the South (48.6 percent) and West (50.7 percent) than in the Northeast (57.1 percent) or Midwest (53.9 percent).
- Among people aged 12 or older, the rates of past month alcohol use in large and small metropolitan areas (54.3 and 51.5 percent, respectively) were higher than in nonmetropolitan areas (43.8 percent). Binge drinking was equally prevalent in large and small metropolitan areas (both 23.1 percent), but was less prevalent in nonmetropolitan areas (20.0 percent).
- The rates of binge alcohol use among youths aged 12 to 17 were 7.3 percent in large metropolitan areas, 7.5 percent in small metropolitan areas, and 7.7 percent in nonmetropolitan areas.

Association with Illicit Drug and Tobacco Use

- As was the case in prior years, the level of alcohol use was associated with illicit drug use in 2011. Among the 15.9 million heavy drinkers aged 12 or older, 31.3 percent were current illicit drug users. Persons who were not current alcohol users were less likely to have used illicit drugs in the past month (4.2 percent) than those who reported (a) current use of alcohol but no binge or heavy use (6.7 percent), (b) binge use but no heavy use (17.2 percent), or (c) heavy use of alcohol (31.3 percent).
- Alcohol consumption levels also were associated with tobacco use. Among heavy alcohol users aged 12 or older, 54.9 percent smoked cigarettes in the past month, while only 18.1 percent of non-binge current drinkers and 15.3 percent of persons who did not drink alcohol in the past month were current smokers. Smokeless tobacco use and cigar use also were more prevalent among heavy drinkers (11.7 and 15.2 percent, respectively) than among non-binge drinkers (1.9 and 4.5 percent) and nondrinkers (1.9 and 2.2 percent).

Driving Under the Influence of Alcohol

- In 2011, an estimated 11.1 percent of persons aged 12 or older drove under the influence of alcohol at least once in the past year (Figure 3.4). This percentage has dropped since 2002, when it was 14.2 percent. The 2011 estimate corresponds to 28.6 million persons.
- Driving under the influence of alcohol differed by age group in 2011. The rate was highest among persons aged 21 to 25 (21.9 percent) (Figure 3.5). An estimated 5.2 percent of 16 or 17 year olds and 13.5 percent of 18 to 20 year olds reported driving under the influence of alcohol in the past year. Beyond age 25, these rates showed a general decline with increasing age.
- Among persons aged 18 to 25, the rate of driving under the influence of alcohol decreased from the rate reported in 2010, from 20.0 to 18.6 percent.
- Among persons aged 12 or older, males were more likely than females (14.6 vs. 7.8 percent) to drive under the influence of alcohol in the past year.

Figure 3.4 Driving Under the Influence of Alcohol in the Past Year among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Figure 3.5 Driving Under the Influence of Alcohol in the Past Year among Persons Aged 16 or Older, by Age: 2011

3.2. Underage Alcohol Use

- In 2011, about 9.7 million persons aged 12 to 20 (25.1 percent of this age group) reported drinking alcohol in the past month. Approximately 6.1 million (15.8 percent) were binge drinkers, and 1.7 million (4.4 percent) were heavy drinkers. The rates for binge and heavy drinking were lower than those in 2010 (16.9 and 5.1 percent, respectively).
- Rates of current, binge, and heavy alcohol use among underage persons declined between 2002 and 2011. The rate of current alcohol use among 12 to 20 year olds went from 28.8 percent in 2002 to 25.1 percent in 2011. The binge drinking rate declined from 19.3 to 15.8 percent, and the rate of heavy drinking declined from 6.2 to 4.4 percent.
- Rates of current alcohol use increased with age among underage persons. In 2011, 2.5 percent of persons aged 12 or 13, 11.3 percent of persons aged 14 or 15, 25.3 percent of 16 or 17 year olds, and 46.8 percent of 18 to 20 year olds drank alcohol during the 30 days before they were surveyed. This pattern by age has been observed since 2002 (Figure 3.6).

Figure 3.6 Current Alcohol Use among Persons Aged 12 to 20, by Age: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- Males aged 12 to 20 in 2011 were more likely than underage females to be current alcohol users (25.6 vs. 24.6 percent), binge alcohol users (17.5 vs. 14.0 percent), or heavy alcohol users (5.6 vs. 3.2 percent) (Figure 3.7). Rates among underage males for current, binge, and heavy drinking were all lower in 2011 than they were in 2010 (28.1, 19.7, and 6.7 percent, respectively). However, the rates in 2011 among underage females did not differ from the rates in 2010 (24.0, 14.0, and 3.4 percent).
- Among persons aged 12 to 20, past month alcohol use rates in 2011 were 18.1 percent among blacks, 18.8 percent among Asians, 20.0 percent among American Indians or Alaska Natives, 22.5 percent among Hispanics, 27.5 percent among those reporting two or more races, and 28.2 percent among whites.
- In 2011, among persons aged 12 to 20, binge drinking was reported by 18.6 percent of whites, 15.9 percent of persons reporting two or more races, 14.0 percent of Hispanics, and 13.9 percent of American Indians or Alaska Natives. Blacks and Asians in this age group were less likely to report binge drinking (9.4 and 9.1 percent, respectively).

Figure 3.7 Current, Binge, and Heavy Alcohol Use among Persons Aged 12 to 20, by Gender: 2011

- Across geographic regions in 2011, the underage current alcohol use rate was higher in the Northeast (30.8 percent) than in the Midwest (25.4 percent), West (24.2 percent), and South (22.7 percent).
- In 2011, the underage current alcohol use rate was similar in large metropolitan areas (24.9 percent), small metropolitan areas (26.1 percent), and nonmetropolitan areas (23.5 percent).
- In 2011, 80.8 percent of current drinkers aged 12 to 20 were with two or more other people the last time they drank alcohol, 14.5 percent were with one other person the last time they drank, and 4.7 percent were alone.
- A majority of underage current drinkers in 2011 reported that their last use of alcohol in the past month occurred either in someone else's home (57.0 percent) or their own home (28.2 percent). Underage females were more likely than males to have been in a restaurant, bar, or club on their last drinking occasion (11.4 vs. 6.6 percent).
- Among underage current drinkers in 2011, 30.3 percent paid for the alcohol the last time they drank, including 7.7 percent who purchased the alcohol themselves and 22.4 percent who gave money to someone else to purchase it.

- In 2011, among underage drinkers who did not pay for the alcohol the last time they drank, the most common source was an unrelated person aged 21 or older (38.2 percent). Other underage persons provided the alcohol on the last occasion for 19.1 percent of underage drinkers. Parents, guardians, or other adult family members provided the last alcohol to 21.4 percent of underage drinkers. Other sources of alcohol for underage drinkers who did not pay included (a) took the alcohol from home (5.9 percent), (b) took it from someone else's home (3.9 percent), and (c) got it some other way (6.8 percent).
- In 2011, underage drinkers were more likely than current alcohol users aged 21 or older to use illicit drugs within 2 hours of alcohol use on their last reported drinking occasion (20.1 vs. 4.9 percent, respectively). The most commonly reported illicit drug used by underage drinkers in combination with alcohol was marijuana, which was used within 2 hours of alcohol use by 19.2 percent of current underage drinkers (1.8 million persons) on their last drinking occasion.

4. Tobacco Use

The National Survey on Drug Use and Health (NSDUH) includes a series of questions about the use of tobacco products, including cigarettes, chewing tobacco, snuff, cigars, and pipe tobacco. Cigarette use is defined as smoking "part or all of a cigarette." For analytic purposes, data for chewing tobacco and snuff are combined and termed "smokeless tobacco."

- In 2011, an estimated 68.2 million Americans aged 12 or older were current (past month) users of a tobacco product. This represents 26.5 percent of the population in that age range. Also, 56.8 million persons (22.1 percent of the population) were current cigarette smokers; 12.9 million (5.0 percent) smoked cigars; 8.2 million (3.2 percent) used smokeless tobacco; and 2.1 million (0.8 percent) smoked tobacco in pipes (Figure 4.1).

Figure 4.1 Past Month Tobacco Use among Persons Aged 12 or Older: 2002-2011

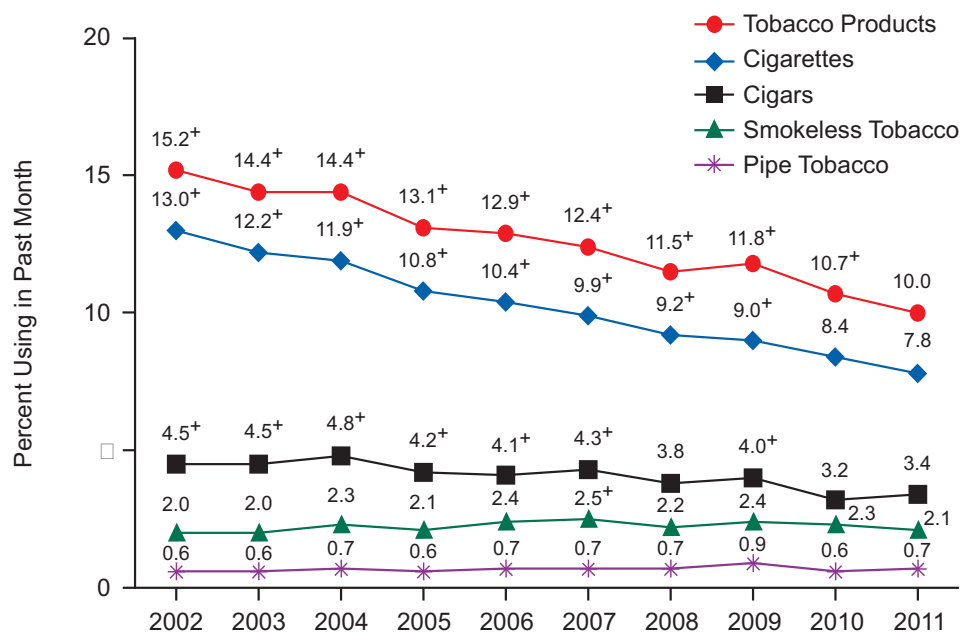

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- The rate of current use of any tobacco product among persons aged 12 or older decreased from 27.5 percent in 2010 to 26.5 percent in 2011. The rate of current use of cigarettes also declined during the same period (from 23.0 to 22.1 percent). Use of smokeless tobacco, cigars, and pipe tobacco did not change significantly over that period. Between 2002 and 2011, past month use of any tobacco product decreased from 30.4 to 26.5 percent, past month cigarette use declined from 26.0 to 22.1 percent, and past month cigar use declined from 5.4 to 5.0 percent. Rates of past month use of smokeless tobacco and pipe tobacco were similar in 2002 and 2011.

Age

- In 2011, young adults aged 18 to 25 had the highest rate of current use of a tobacco product (39.5 percent) compared with youths aged 12 to 17 and adults aged 26 or older (10.0 and 26.3 percent, respectively). Young adults had the highest usage rates of each of the specific tobacco products as well. In 2011, the rates of past month use among young adults were 33.5 percent for cigarettes, 10.9 percent for cigars, 5.4 percent for smokeless tobacco, and 1.9 percent for pipe tobacco.
- The rate of current use of a tobacco product by young adults declined from 40.9 percent in 2010 to 39.5 percent in 2011. Between 2002 and 2011, there was a significant decrease in the rates for current use of tobacco products and cigarettes among young adults; in 2002, the rates were 45.3 and 40.8 percent, respectively. The rate of current use of pipe tobacco by young adults increased from 1.1 percent in 2002 to 1.9 percent in 2011.
- The rate of past month tobacco use among 12 to 17 year olds declined from 15.2 percent in 2002 to 10.0 percent in 2011, including a decline from 2010 (10.7 percent) to 2011 (Figure 4.2). The rate of past month cigarette use among 12 to 17 year olds declined from 13.0 percent in 2002 to 9.0 percent in 2009 and to 7.8 percent in 2011. The rate of past month smokeless tobacco use among 12 to 17 year olds remained steady between 2002 and 2011 (2.0 and 2.1 percent, respectively).
- Across age groups, current cigarette use was highest among persons aged 18 to 20 (31.6 percent), those aged 21 to 25 (34.7 percent), those aged 26 to 29 (33.7 percent), and those aged 30 to 34 (29.7 percent) (Figure 4.3). About one fifth (19.7 percent) of persons aged 35 or older in 2011 smoked cigarettes in the past month.

Figure 4.2 Past Month Tobacco Use among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Figure 4.3 Past Month Cigarette Use among Persons Aged 12 or Older, by Age: 2011

Gender

- In 2011, current use of a tobacco product among persons aged 12 or older was reported by a higher percentage of males (32.3 percent) than females (21.1 percent). Males also had higher rates of past month use than females of each specific tobacco product: cigarettes (24.3 percent of males vs. 19.9 percent of females), cigars (8.2 vs. 2.0 percent), smokeless tobacco (6.2 vs. 0.4 percent), and pipe tobacco (1.4 vs. 0.3 percent).
- The 2011 rate of any tobacco use by males (32.3 percent) was lower than the rate in 2010 (33.7 percent).
- Among youths aged 12 to 17, the rates of current cigarette smoking in 2011 were similar for males (8.2 percent) and females (7.3 percent) (Figure 4.4). The rates in 2011 for males and females did not differ from corresponding rates in 2010 (8.6 and 8.2 percent, respectively). The prevalence declined from 2009 to 2011 for both males and females. From 2002 to 2011, the rate of current cigarette smoking among youths decreased for both males (from 12.3 to 8.2 percent) and females (from 13.6 to 7.3 percent).

Figure 4.4 Past Month Cigarette Use among Youths Aged 12 to 17, by Gender: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- After declining from 40.4 percent in 2009 to 38.1 percent in 2010, the rate of current cigarette smoking among male young adults aged 18 to 25 held steady in 2011 (38.3 percent). The rate of cigarette smoking declined for female young adults between 2010 and 2011 (from 30.5 to 28.7 percent). Between 2002 and 2011, the rate of cigarette use among young adults declined for both males (from 44.4 to 38.3 percent) and females (from 37.1 to 28.7 percent).

Pregnant Women

- About one in six pregnant women aged 15 to 44 had smoked cigarettes in the past month, based on combined data for 2010 and 2011. The rate of past month cigarette use was lower among women who were pregnant (17.6 percent) than it was among women who were not pregnant (25.4 percent) (Figure 4.5). This pattern was also evident among women aged 18 to 25 (22.4 vs. 29.9 percent for pregnant and nonpregnant women, respectively) and among women aged 26 to 44 (14.3 vs. 25.7 percent, respectively).
- Two-year moving average rates indicate that current cigarette use among women aged 15 to 44 decreased from 30.7 percent in 2002-2003 to 25.4 percent in 2010-2011 for those who were not pregnant (Figure 4.5). However, the prevalence of cigarette use among pregnant women in that age range was similar between 2002-2003 (18.0 percent) and 2010-2011 (17.6 percent).

Figure 4.5 Past Month Cigarette Use among Women Aged 15 to 44, by Pregnancy Status: Combined Years 2002-2003 to 2010-2011

⁺ Difference between this estimate and the 2010-2011 estimate is statistically significant at the .05 level.

Race/Ethnicity

- In 2011, the prevalence of current use of a tobacco product among persons aged 12 or older was 13.0 percent for Asians, 20.4 percent for Hispanics, 26.2 percent for blacks, 28.6 percent for whites, 36.1 percent for persons who reported two or more races, and 43.0 percent for American Indians or Alaska Natives. There were no statistically significant changes in past month use of a tobacco product between 2010 and 2011 for any of these racial/ethnic groups.
- In 2011, current cigarette smoking among youths aged 12 to 17 and young adults aged 18 to 25 was more prevalent among whites than blacks (9.3 vs. 4.9 percent for youths and 37.8 vs. 25.7 percent for young adults).
- Among Hispanics, the rate of current cigarette smoking decreased from 7.9 percent in 2010 to 6.1 percent in 2011 for youths aged 12 to 17. Rates of current cigarette smoking were 28.4 percent for young adults aged 18 to 25 and 18.4 percent among those aged 26 or older. Among Hispanics in these two adult age groups, rates of current cigarette use in 2011 were not significantly different from corresponding rates in 2010.
- Current cigarette smoking rates across age groups held steady for Asians between 2010 and 2011. The current cigarette smoking rate for Asian youths aged 12 to 17 was 3.6 percent in 2010 and 3.3 percent in 2011. The rates in 2010 and 2011 for Asian adults were 21.1 and 22.7 percent, respectively, for young adults aged 18 to 25 and were 10.1 and 10.6 percent for those aged 26 or older.
- The prevalence of current cigarette smoking for American Indian or Alaska Native youths aged 12 to 17 was 12.3 percent in 2011. This rate was not significantly different from the rate in 2010 (14.9 percent).

Education

- Since 2002, cigarette smoking in the past month has been less prevalent among adults who were college graduates compared with those with less education. Among adults aged 18 or older, current cigarette use in 2011 was reported by 33.7 percent of those who had not completed high school, 28.3 percent of high school graduates who did not attend college, 25.9 percent of persons with some college, and 11.7 percent of college graduates. These rates were similar to the 2010 rates by educational attainment.

College Students

- Among young adults 18 to 22 years old, full-time college students were less likely to be current cigarette smokers than their peers who were not enrolled full time in college. Cigarette use in the past month in 2011 was reported by 23.8 percent of full-time college students, which was less than the rate of 39.2 percent for those not enrolled full time. The same pattern was found among both males and females in this age range.

- Among males aged 18 to 22 who were full-time college students, the rate of cigarette use remained steady between 2010 and 2011 (27.3 and 26.6 percent, respectively). The rate of past month use of cigars decreased among male full-time college students aged 18 to 22 from 2010 to 2011 (from 18.5 to 14.9 percent).

Employment

- In 2011, current cigarette smoking was more common among unemployed adults aged 18 or older than among adults who were working full time or part time (40.7 vs. 23.3 and 22.9 percent, respectively). Cigar smoking followed a similar pattern, with 8.9 percent of unemployed adults reporting past month use compared with 5.6 percent of full-time workers and 5.8 percent of part-time workers.
- Current use of smokeless tobacco in 2011 was higher among adults aged 18 or older who were employed full time and those who were unemployed (4.3 and 3.5 percent, respectively) than among adults who were employed part time (2.5 percent) and those in the "other" employment category, which includes persons not in the labor force (2.1 percent). These rates were similar to the 2010 smokeless tobacco use rates for these employment categories.

Geographic Area

- In 2011, current cigarette smoking among persons aged 12 or older was lower in the West (18.1 percent) than in the Northeast (22.2 percent), the South (23.2 percent), and the Midwest (24.2 percent). Use of smokeless tobacco was highest in the Midwest (4.3 percent), followed by the South (3.7 percent), then the West (2.4 percent), then the Northeast (1.9 percent).
- As in previous years, the rates of tobacco use in 2011 were associated with county type among persons aged 12 or older. The rate of current cigarette use was 20.4 percent in large metropolitan areas, 22.8 percent in small metropolitan areas, and 26.4 percent in nonmetropolitan areas. Use of smokeless tobacco in the past month in 2011 among persons aged 12 or older was lowest in large metropolitan areas (2.0 percent). In small metropolitan areas, the current smokeless tobacco use rate was 4.0 percent; in nonmetropolitan areas, it was 5.7 percent.

Association with Illicit Drug and Alcohol Use

- Use of illicit drugs and alcohol was more common among current cigarette smokers than among nonsmokers in 2011, as in prior years since 2002. Among persons aged 12 or older, 22.1 percent of past month cigarette smokers reported current use of an illicit drug compared with 4.9 percent of persons who were not current cigarette smokers. Over half of youths aged 12 to 17 (57.6 percent, or 1.1 million youths) who smoked cigarettes in the past month also used an illicit drug compared with 6.1 percent of youths who did not smoke cigarettes.
- Past month alcohol use was reported by 66.5 percent of current cigarette smokers compared with 47.6 percent of those who did not use cigarettes in the past month. The association also was found with binge drinking (42.5 percent of current cigarette smokers vs. 17.0 percent of current nonsmokers) and heavy drinking (15.3 vs. 3.6 percent, respectively).

Frequency of Cigarette Use

- Among the 56.8 million current cigarette smokers aged 12 or older in 2011, 34.5 million (60.7 percent) used cigarettes daily. The percentage of daily cigarette smokers among past month cigarette users increased with age (22.7 percent of past month cigarette users aged 12 to 17, 45.3 percent of those aged 18 to 25, and 66.5 percent of those aged 26 or older).
- The percentage of current smokers who used cigarettes daily decreased from 63.4 percent in 2002 to 60.7 percent in 2011. During the same time period, daily cigarette use among current smokers aged 12 to 17 decreased from 31.8 to 22.7 percent. Daily cigarette use among young adult smokers aged 18 to 25 also declined (from 51.8 to 45.3 percent). Percentages of adult current cigarette smokers aged 26 or older who used cigarettes daily were 68.8 percent in 2002 and 66.5 percent in 2011.
- Less than half (43.8 percent) of daily smokers aged 12 or older reported smoking 16 or more cigarettes per day (i.e., approximately one pack or more). The percentage of daily smokers who smoked at least one pack of cigarettes per day increased with age, from 14.7 percent among of daily smokers aged 12 to 17 to 26.1 percent of those aged 18 to 25, then to 47.4 percent of those aged 26 or older (Figure 4.6).
- The percentage of daily smokers aged 26 or older who smoked one or more packs of cigarettes per day was lower in 2011 (47.4 percent) than in 2002 to 2008. Declines also were seen from 2002 to 2011 for youths aged 12 to 17 (from 39.0 to 26.1 percent) and young adults (from 39.0 to 26.1 percent).

Figure 4.6 Past Month Smokers of One or More Packs of Cigarettes per Day among Daily Smokers, by Age Group: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

5. Initiation of Substance Use

Information on substance use initiation, also known as incidence or first-time use, is important for policymakers and researchers. Measures of initiation are often leading indicators of emerging patterns of substance use. They provide valuable information that can be used to assess the effectiveness of current prevention programs and to focus prevention efforts.

With its large sample size and oversampling of youths aged 12 to 17 and young adults aged 18 to 25, the National Survey on Drug Use and Health (NSDUH) provides estimates of recent or past year initiation of use of illicit drugs, tobacco, and alcohol based on reported age and on year and month at first use. Recent or past year initiates are defined as those who reported use of a particular substance for the first time within 12 months preceding the date of interview. There is a caveat to the past year initiation measure worth mentioning. Because the survey interviews persons aged 12 or older, the past year initiation estimates reflect only a portion of the initiation that occurred at age 11 and none of the initiation that occurred at age 10 or younger. This underestimation primarily affects estimates of initiation for cigarettes, alcohol, and inhalants because they tend to be initiated at a younger age than other substances. See Section B.4.1 in Appendix B for further discussion of the methods and bias in initiation estimates.

This chapter includes estimates of the number and rate of past year initiation of illicit drug, tobacco, and alcohol use among the total population aged 12 or older and by selected age and gender categories from the 2011 NSDUH, comparing with prior year(s). Also included are initiation estimates that pertain to persons at risk for initiation. Persons at risk for initiation of use of a particular substance are those who never used the substance in their lifetime plus those who used that substance for the first time in the 12 months prior to the interview. In other words, persons at risk are those who had never used as of 12 months prior to the interview date. Some analyses are based on the age at the time of interview, and others focus on the age at the time of first substance use. Readers need to be aware of these alternative estimation approaches when interpreting NSDUH incidence estimates and pay close attention to the approach used in each situation. Titles and notes on figures and associated detailed tables document which method applies.

For trend measurement, initiation estimates for each year (2002 to 2011) are produced independently based on the data from the survey conducted that year. Estimates of trends in incidence based on longer recall periods have not been considered because of concerns about their validity (Gfroerer, Hughes, Chromy, Heller, & Packer, 2004).

Regarding the age at first use estimates, means, as measures of central tendency, are heavily influenced by the presence of extreme values in the data for persons aged 12 or older. To reduce the effect of extreme values, the mean age at initiation was calculated for persons aged 12 to 49, leaving out those few respondents who were past year initiates at age 50 or older. Including data from initiates aged 26 to 49 in this broad age group also can cause instability of estimates of the mean age at initiation among persons aged 12 to 49, but this effect is less than that of including data from initiates aged 50 or older. Nevertheless, caution is needed in interpreting these trends for persons aged 12 to 49. Section B.4.1 in Appendix B also discusses this issue. Note, however, that this constraint affects only the estimates of mean age at initiation.

Other estimates in this chapter, including the numbers and percentages of past year initiates, are not affected by extreme ages at initiation and therefore are reported for all persons aged 12 or older.

Another important consideration in examining incidence estimates across different drug categories is that substance users typically initiate use of different substances at different times in their lives. Thus, the estimates for past year initiation of each specific illicit drug cannot be added to obtain the total number of overall illicit drug initiates because some of the initiates previously had used other drugs. The initiation estimate for any illicit drug represents the past year initiation of use of a specific drug that was not preceded by use of other illicit drugs. For example, a respondent who reported initiating marijuana use in the past 12 months is counted as a marijuana initiate. The same respondent also can be counted as an illicit drug initiate with marijuana as the first drug only if his or her marijuana use initiation was not preceded by use of any other drug (cocaine, heroin, hallucinogens, inhalants, pain relievers, tranquilizers, stimulants, or sedatives). In addition, past year initiates of lysergic acid diethylamide (LSD), phencyclidine (PCP), or Ecstasy use are counted as past year initiates of any hallucinogen use only if they had not previously used other hallucinogens. Similarly, past year initiates of crack cocaine, OxyContin[®], or methamphetamine use are counted as past year initiates for the broader category (i.e., any cocaine, nonmedical use of pain relievers, or nonmedical use of stimulants, respectively) only if they did not report previous use (or nonmedical use) for the broader category.

Initiation of Illicit Drug Use

- In 2011, about 3.1 million persons aged 12 or older used an illicit drug for the first time within the past 12 months; this averages to about 8,400 new users per day. This estimate was not significantly different from the number in 2010 (3.0 million). Over half of initiates (55.5 percent) were younger than age 18 when they first used, and 55.8 percent of new users were female. The 2011 average age at initiation among persons aged 12 to 49 was 18.1 years, which was similar to the 2010 estimate (19.1 years). See Section B.4.1 in Appendix B for a discussion of the effects of older adult initiates on estimates of mean age at first use.
- Of the estimated 3.1 million persons aged 12 or older in 2011 who used illicit drugs for the first time within the past 12 months, a majority reported that their first drug was marijuana (67.5 percent) (Figure 5.1). More than 1 in 5 initiated with nonmedical use of psychotherapeutics (22.0 percent, including 14.0 percent with pain relievers, 4.2 percent with tranquilizers, 2.6 percent with stimulants, and 1.2 percent with sedatives). A notable proportion reported inhalants (7.5 percent) as their first illicit drug, and a small proportion used hallucinogens (2.8 percent). Except for marijuana, all of the above percentages of first illicit drug use were similar to the corresponding percentages in 2010. The percentage whose first illicit drug was marijuana in 2011 was greater than the percentage in 2010 (62.0 percent).

Figure 5.1 First Specific Drug Associated with Initiation of Illicit Drug Use among Past Year Illicit Drug Initiates Aged 12 or Older: 2011

3.1 Million Initiates of Illicit Drugs

Note: The percentages do not add to 100 percent due to rounding or because a small number of respondents initiated multiple drugs on the same day. The first specific drug refers to the one that was used on the occasion of first-time use of any illicit drug.

Comparison, by Drug

- In 2011, the specific illicit drug category with the largest number of recent initiates among persons aged 12 or older was marijuana use (2.6 million), followed by nonmedical use of pain relievers (1.9 million), nonmedical use of tranquilizers (1.2 million), Ecstasy (0.9 million), and cocaine and stimulants (0.7 million each) (Figure 5.2).
- Among persons aged 12 to 49 in 2011, the average age at first use was 16.4 years for inhalants, 17.5 years for marijuana, 19.6 years for Ecstasy, 20.1 years for cocaine, 21.8 years for pain relievers, 22.1 years for heroin, 22.2 years for stimulants, and 24.6 years for tranquilizers (Figure 5.3).

Figure 5.2 Past Year Initiates of Specific Illicit Drugs among Persons Aged 12 or Older: 2011

Note: Numbers refer to persons who used a specific drug for the first time in the past year, regardless of whether initiation of other drug use occurred prior to the past year.

Figure 5.3 Mean Age at First Use for Specific Illicit Drugs among Past Year Initiates Aged 12 to 49: 2011

Marijuana

- In 2011, there were 2.6 million persons aged 12 or older who had used marijuana for the first time within the past 12 months; this averages to about 7,200 new users each day. The 2011 estimate was similar to the estimates in 2009 and 2010 (2.4 million each), but higher than the estimates in 2002 through 2008 (Figure 5.4). In 2011, the majority (57.7 percent) of the 2.6 million recent marijuana initiates were younger than age 18 when they first used. Among all youths aged 12 to 17, an estimated 5.5 percent had used marijuana for the first time within the past year, which was similar to the rate in 2010 (5.2 percent).

Figure 5.4 Past Year Marijuana Initiates among Persons Aged 12 or Older and Mean Age at First Use of Marijuana among Past Year Marijuana Initiates Aged 12 to 49: 2002-2011

^x Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

¹ Mean-age-at-first-use estimates are for recent initiates aged 12 to 49.

- In 2011, among persons aged 12 or older, an estimated 1.5 million first-time past year marijuana users initiated prior to the age of 18. This estimate was about the same as the corresponding estimates in 2010 (1.4 million) and 2009 (1.5 million).
- As a percentage of those aged 12 to 17 who had not used marijuana prior to the past year (i.e., those at risk for initiation), the youth marijuana initiation rate in 2011 (6.3 percent) was similar to the rate in 2010 (5.9 percent).
- In 2011, the average age at first marijuana use among recent initiates aged 12 to 49 was 17.5 years, which was similar to the average age in 2010 (18.4 years) and 2004 through 2008, but was higher than the average ages in 2002, 2003, and 2009 (Figure 5.4). Section B.4.1 in Appendix B discusses the potential instability of estimates of older adult initiation and the impact on estimates of mean age at first use.
- In 2011, among recent initiates aged 12 or older who initiated marijuana use prior to the age 21, the mean age at first use was 16.2 years, which was the same as the mean age in 2010.

Cocaine

- In 2011, there were 670,000 persons aged 12 or older who had used cocaine for the first time within the past 12 months; this averages to approximately 1,800 initiates per day. This estimate was similar to the number in 2010 (642,000), 2009 (623,000), and 2008 (724,000). The annual number of cocaine initiates declined from 1.0 million in 2002 to 670,000 in 2011. The number of initiates of crack cocaine declined during this period from 337,000 to 76,000.
- In 2011, most (74.7 percent) of the 0.7 million recent cocaine initiates were 18 or older when they first used. The average age at first use among recent initiates aged 12 to 49 was 20.1 years. The average age estimates have remained fairly stable since 2002.

Heroin

- In 2011, there were 178,000 persons aged 12 or older who had used heroin for the first time within the past 12 months. Although this number was similar to the estimates in 2010 (142,000) and 2009 (187,000), the 2011 estimate was higher than the estimates during 2005 to 2007 (ranging from 90,000 to 108,000 per year). The average age at first use among recent initiates aged 12 to 49 was 22.1 years, which was similar to the 2010 estimate (21.4 years).

Hallucinogens

- In 2011, there were 1.1 million persons aged 12 or older who had used hallucinogens for the first time within the past 12 months (Figure 5.5). This estimate was similar to the estimates from 2006 to 2010 (ranging from 1.1 million to 1.3 million), but was higher than the estimates from 2003 to 2005 (ranging from 886,000 to 953,000).

Figure 5.5 Past Year Hallucinogen Initiates among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- The number of past year initiates of LSD aged 12 or older was 358,000 in 2011, which was similar to the number in 2010 (381,000), but higher than the estimates from 2003 to 2007 (ranging from 200,000 to 271,000) (Figure 5.5). Past year initiates of PCP decreased from 123,000 in 2002 to 48,000 in 2011.
- The number of past year initiates of Ecstasy was 922,000 in 2011, which was similar to the number in 2010 (949,000), but lower than the number in 2009 (1.1 million) (Figure 5.5). The estimate was 1.2 million in 2002, declined to 642,000 in 2003, and increased by about 50 percent between 2005 (615,000) and 2011 (922,000). Most (61.3 percent) of the recent Ecstasy initiates in 2011 were aged 18 or older at the time they first used Ecstasy. Among past year initiates aged 12 to 49, the average age at initiation of Ecstasy in 2011 was 19.6 years, which was similar to the average age in 2010 (19.4 years), but lower than the average age in 2002 (21.2 years).
- In 2011, among persons aged 12 or older, the number of first-time past year Ecstasy users who initiated use prior to the age of 18 was 357,000. This estimate was higher than the estimate in 2005 (209,000).

Inhalants

- In 2011, there were 719,000 persons aged 12 or older who had used inhalants for the first time within the past 12 months, which was lower than the numbers in prior years from 2002 to 2005 (ranging from 849,000 to 877,000). An estimated 67.1 percent of past year initiates of inhalants in 2011 were under age 18 when they first used. The average age at first use among recent initiates aged 12 to 49 was similar in 2010 and 2011 (16.3 and 16.4 years, respectively).

Psychotherapeutics

- Psychotherapeutics include the nonmedical use of any prescription-type pain relievers, tranquilizers, stimulants, or sedatives. Over-the-counter substances are not included. In 2011, there were 2.3 million persons aged 12 or older who used psychotherapeutics nonmedically for the first time within the past year, which averages to around 6,400 initiates per day. The number of new nonmedical users of psychotherapeutics in 2011 was similar to the 2010 estimate (2.4 million), but was lower than the 2004 estimate (2.8 million). The number of new nonmedical users of pain relievers in 2011 (1.9 million) was lower than the numbers in 2002 through 2005 and in 2008 and 2009 (ranging from 2.2 million to 2.5 million). In 2011, the number of initiates was 1.2 million for tranquilizers, 670,000 for stimulants, and 159,000 for sedatives.
- In 2011, the average age at first nonmedical use of any psychotherapeutics among recent initiates aged 12 to 49 was 22.4 years. More specifically, it was 21.8 years for pain relievers, 22.0 years for sedatives, 22.2 years for stimulants, and 24.6 years for tranquilizers. All of these estimates were similar to the corresponding estimates in 2010.
- In 2011, the number of new nonmedical users of OxyContin[®] aged 12 or older was 483,000, which was similar to the 2010 estimate of 600,000. The average age at first use of OxyContin[®] among past year initiates aged 12 to 49 was the same in 2010 and 2011 (22.8 years).
- The number of recent new users of methamphetamine among persons aged 12 or older was 133,000 in 2011 (Figure 5.6), which was similar to the 2010 estimate (107,000), but lower than the 2002 to 2006 estimates (ranging from 192,000 to 318,000). The average age of new methamphetamine users aged 12 to 49 in 2011 was 17.8 years, which was not significantly different from the corresponding estimates for 2002 and 2003 and from 2005 to 2010, but was lower than the 2004 estimate (20.6 years).

Alcohol

- In 2011, there were 4.7 million persons aged 12 or older who had used alcohol for the first time within the past 12 months; this averages to approximately 12,900 initiates per day.
- Most (82.9 percent) of the 4.7 million recent alcohol initiates were younger than age 21 at the time of initiation. Approximately 61.2 percent initiated prior to age 18.

Figure 5.6 Past Year Methamphetamine Initiates among Persons Aged 12 or Older and Mean Age at First Use of Methamphetamine among Past Year Methamphetamine Initiates Aged 12 to 49: 2002-2011

* Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

¹ Mean-age-at-first-use estimates are for recent initiates aged 12 to 49.

- In 2011, the average age at first alcohol use among recent initiates aged 12 to 49 was 17.1 years, which was the same as the 2010 estimate, but higher than the 2002 to 2006 estimates (ranging from 16.4 to 16.6 years). The mean age at first use among recent initiates aged 12 or older who initiated use prior to the age of 21 was 15.9 years, which was similar to the 2010 estimate of 16.0 years.

Tobacco

- The number of persons aged 12 or older who smoked cigarettes for the first time within the past 12 months was 2.4 million in 2011, which was the same as the estimate in 2010, but was higher than the estimates for 2002 (1.9 million), 2003 (2.0 million), and 2004 (2.1 million) (Figure 5.7). The 2011 estimate averages out to approximately 6,600 new cigarette smokers every day. The majority of new cigarette smokers in 2011 initiated prior to age 18 (55.7 percent).

Figure 5.7 Past Year Cigarette Initiates among Persons Aged 12 or Older, by Age at First Use: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- In 2002 and 2011, the numbers of cigarette initiates who were under age 18 when they first used were the same (1.3 million). However, the number of cigarette initiates who began smoking at age 18 or older increased from 623,000 in 2002 to 1.1 million in 2011.
- In 2011, among recent initiates aged 12 to 49, the average age of first cigarette use was 17.2 years, which was similar to the average in 2010 (17.3 years).
- Of those aged 12 or older who had not smoked cigarettes prior to the past year (i.e., those at risk for initiation), the past year initiation rate for cigarettes was 2.4 percent in 2011, which was similar to the rate in 2010 (2.6 percent). Among youths aged 12 to 17 who had not smoked cigarettes prior to the past year, the incidence rate in 2011 was 5.5 percent, which was similar to the 2010 rate (5.9 percent). Among males aged 12 to 17 who had never smoked prior to the past year, past year initiation rates in 2002 to 2010 were not significantly different from the rate in 2011 (Figure 5.8). However, the past year initiation rate among females aged 12 to 17 who were at risk for initiation was lower in 2011 (5.5 percent) than in 2002 to 2006 or in 2008.

Figure 5.8 Past Year Cigarette Initiation among Youths Aged 12 to 17 Who Had Never Smoked Prior to the Past Year, by Gender: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- In 2011, the number of persons aged 12 or older who had started smoking cigarettes daily within the past 12 months was 878,000. This estimate was similar to the 2010 estimate (962,000), but was lower than the estimates in 2003, 2004, 2006, and 2009 (ranging from 1.0 million to 1.1 million). Of the new daily smokers in 2011, 38.0 percent, or 334,000 persons, were younger than age 18 when they started smoking daily. This figure averages to approximately 916 initiates of daily smoking under the age of 18 every day.
- The average age of first daily smoking among new daily smokers aged 12 or older was 19.1 years in 2010 and 2011. Among males and females, the average age at first use was similar in 2010 and 2011 (18.6 and 19.2 years for males, 19.8 and 19.0 years for females).
- In 2011, there were 2.8 million persons aged 12 or older who had used cigars for the first time in the past 12 months, which was similar to the 2010 estimate (3.0 million). However, the 2011 estimate was lower than the 2005 estimate (3.3 million). Among past year cigar initiates aged 12 to 49, the average age at first use was 19.6 years in 2011, which was similar to the estimate in 2010 (20.5 years).

- The number of persons aged 12 or older initiating use of smokeless tobacco in the past year was 1.3 million in 2011, which was similar to the estimates in 2005 to 2010 (ranging from 1.1 million to 1.5 million). In 2011, over three quarters (77.6 percent) of new initiates were male, and over two fifths (43.7 percent) were under age 18 when they first used.
- In 2011, the average age at first smokeless tobacco use among recent initiates aged 12 to 49 was 19.8 years, which was similar to the 2010 estimate (19.3 years). Among both males and females, the average ages at first use of smokeless tobacco were similar in 2010 and 2011 (19.1 and 20.1 years for males, 19.9 and 18.9 years for females).

6. Youth Prevention-Related Measures

Research has shown that substance use by adolescents can often be prevented through interventions involving risk and protective factors associated with the onset or escalation of use (Catalano, Hawkins, Berglund, Pollard, & Arthur, 2002). Risk and protective factors include variables that operate at different stages of development and reflect different domains of influence, including the individual, family, peer, school, community, and societal levels (Hawkins, Catalano, & Miller, 1992; Robertson, David, & Rao, 2003). Interventions to prevent substance use generally are designed to ameliorate the influence of risk factors and enhance the effectiveness of protective factors.

The National Survey on Drug Use and Health (NSDUH) includes questions for youths aged 12 to 17 to measure the risk and protective factors that may affect the likelihood that they will engage in substance use. This chapter presents findings on youth prevention-related measures, comparing the findings from 2002 to 2011. Included are measures of the perceived risk of substance use (cigarettes, alcohol, and illicit drugs), perceived availability of substances, being approached by someone selling drugs, perceived parental disapproval of youth substance use, parental involvement, feelings about peer substance use, involvement in fighting and delinquent behavior, participation in religious and other activities, and exposure to substance use prevention messages and programs. Also presented are findings on the associations between selected measures of risk and protective factors and substance use from NSDUH, although the cross-sectional nature of these data preclude making any causal connections between these risk and protective factors and substance use.

Perceived Risk of Substance Use

One factor that can influence whether youths will use tobacco, alcohol, or illicit drugs is the extent to which they believe these substances might cause them harm. NSDUH respondents were asked how much they thought people risk harming themselves physically and in other ways when they use various substances in certain amounts or frequencies. Response choices for these items were "great risk," "moderate risk," "slight risk," or "no risk."

- In 2011, 66.2 percent of youths aged 12 to 17 perceived great risk in smoking one or more packs of cigarettes per day, 64.8 percent perceived great risk in having four or five drinks of an alcoholic beverage nearly every day, and 40.7 percent perceived great risk in having four or five drinks once or twice a week. For marijuana, 44.8 percent of youths perceived great risk in smoking marijuana once or twice a week, and 27.6 percent perceived great risk in smoking marijuana once a month. The percentages of youths who perceived great risk in using other drugs once or twice a week were 79.7 percent for heroin, 78.1 percent for cocaine, and 70.4 percent for LSD.

- The percentages of youths reporting binge alcohol use and the use of cigarettes and marijuana in the past month were lower among those who perceived great risk in using these substances than among those who did not perceive great risk. For instance, in 2011, past month binge drinking (consumption of five or more drinks of an alcoholic beverage on a single occasion on at least 1 day in the past 30 days) was reported by 4.5 percent of youths aged 12 to 17 who perceived great risk from "having five or more drinks of an alcoholic beverage once or twice a week," which was lower than the rate (9.5 percent) for youths who saw moderate, slight, or no risk from having five or more drinks of an alcoholic beverage once or twice a week (Figure 6.1). Past month marijuana use was reported by 0.9 percent of youths who saw great risk in smoking marijuana once a month compared with 10.7 percent of youths who saw moderate, slight, or no risk.

Figure 6.1 Past Month Binge Drinking and Marijuana Use among Youths Aged 12 to 17, by Perceptions of Risk: 2011

- Trends in substance use often coincide with trends in perceived risk. Increases in perceived risk typically precede or occur simultaneously with decreases in use, and vice versa. For example, the proportion of youths aged 12 to 17 who reported perceiving great risk from smoking one or more packs of cigarettes per day increased from 63.1 percent in 2002 to 69.5 percent in 2008, then declined to 65.5 percent in 2009; this rate remained unchanged between 2009 and 2011 (66.2 percent) (Figure 6.2). Consistent with increases in the perceived risk of cigarette smoking, the rate of past month adolescent cigarette smoking decreased from 13.0 percent in 2002 to 7.8 percent in 2011.

Figure 6.2 Perceived Great Risk of Cigarette and Alcohol Use among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- The percentage of youths aged 12 to 17 indicating great risk in having four or five drinks of an alcoholic beverage nearly every day increased from 62.2 percent in 2002 to 64.8 percent in 2011 (Figure 6.2). The percentage of youths perceiving great risk in having five or more drinks of an alcoholic beverage once or twice a week increased from 38.2 percent in 2002 to 40.7 percent in 2011. Consistent with these increases in perceived risk among youths aged 12 to 17, there were decreases between 2002 and 2011 in the rates of past month heavy alcohol use (from 2.5 to 1.5 percent) and binge alcohol use (from 10.7 to 7.4 percent).
- The percentage of youths aged 12 to 17 indicating great risk in smoking marijuana once a month decreased from 34.4 percent in 2007 to 27.6 percent in 2011, and the rate of youths perceiving great risk in smoking marijuana once or twice a week also decreased from 54.6 percent in 2007 to 44.8 percent in 2011 (Figure 6.3). Consistent with decreasing trends in the perceived risk of marijuana use, the prevalence of past month marijuana use among youths increased between 2007 (6.7 percent) and 2011 (7.9 percent).
- Between 2002 and 2011, the percentage of youths aged 12 to 17 perceiving great risk from using a substance once or twice a week declined for the following substances: heroin (from 82.5 to 79.7 percent), cocaine (from 79.8 to 78.1 percent), LSD (from 76.2 to 70.4 percent), and marijuana (from 51.5 to 44.8 percent) (Figure 6.4). The rates remained unchanged between 2010 and 2011 for heroin, cocaine, and LSD, but declined for marijuana (from 47.2 to 44.8 percent). Youths were less likely to perceive great risk for smoking marijuana than for use of the other listed substances.

Figure 6.3 Perceived Great Risk of Marijuana Use among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Figure 6.4 Perceived Great Risk of Use of Selected Illicit Drugs Once or Twice a Week among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Perceived Availability

- In 2011, about half (47.7 percent) of youths aged 12 to 17 reported that it would be "fairly easy" or "very easy" for them to obtain marijuana if they wanted some (Figure 6.5). About one in nine (10.7 percent) indicated that heroin would be fairly or very easily available, and 12.2 percent reported so for LSD. Between 2002 and 2011, there were decreases in the perceived easy availability of marijuana (from 55.0 to 47.7 percent), cocaine (from 25.0 to 17.5 percent), crack (from 26.5 to 18.2 percent), LSD (from 19.4 to 12.2 percent), and heroin (from 15.8 to 10.7 percent).
- Youths aged 12 to 17 in 2011 who perceived that it was easy to obtain specific illicit drugs were more likely to be past month users of illicit drugs or marijuana than were youths who perceived that obtaining specific illicit drugs would be fairly difficult, very difficult, or probably impossible. For example, 18.7 percent of youths who reported that marijuana would be easy to obtain were past month illicit drug users, but only 2.8 percent of those who thought marijuana would be more difficult to obtain were past month users. Similarly, 15.7 percent of youths who reported that marijuana would be easy to obtain were past month marijuana users, but only 1.2 percent of those who thought marijuana would be more difficult to obtain were past month users.

Figure 6.5 Perceived Availability of Selected Illicit Drugs among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- The percentage of youths who reported that marijuana, cocaine, crack, heroin, and LSD would be easy to obtain increased with age in 2011. For instance, 19.3 percent of those aged 12 or 13 said it would be fairly or very easy to obtain marijuana compared with 50.0 percent of those aged 14 or 15 and 70.7 percent of those aged 16 or 17.
- In 2011, 13.8 percent of youths aged 12 to 17 indicated that they had been approached by someone selling drugs in the past month. This rate was similar to the 2010 rate (14.3 percent), but was lower than the rate reported in 2002 (16.7 percent).

Perceived Parental Disapproval of Substance Use

- Most youths aged 12 to 17 believed their parents would "strongly disapprove" of their using substances. In 2011, 89.3 percent of youths reported that their parents would strongly disapprove of their trying marijuana or hashish once or twice; this was similar to the 89.1 percent reported in 2002. Most youths in 2011 (90.5 percent) reported that their parents would strongly disapprove of their having one or two drinks of an alcoholic beverage nearly every day, which was the same as the rate in 2010 and was higher than the rate in 2002 (89.0 percent). In 2011, 93.2 percent of youths reported that their parents would strongly disapprove of their smoking one or more packs of cigarettes per day, which was similar to the rate reported in 2010 (92.6 percent), but was higher than the 89.5 percent reported in 2002.
- Youths aged 12 to 17 who believed their parents would strongly disapprove of their using substances were less likely to use that substance than were youths who believed their parents would somewhat disapprove or neither approve nor disapprove. For instance, in 2011, past month cigarette use was reported by 5.5 percent of youths who perceived strong parental disapproval if they were to smoke one or more packs of cigarettes per day compared with 37.1 percent of youths who believed their parents would not strongly disapprove. Also, past month marijuana use was much less prevalent among youths who perceived strong parental disapproval for trying marijuana or hashish once or twice than among those who did not perceive this level of disapproval (5.0 vs. 31.5 percent, respectively).

Attitudes toward Peer Substance Use

- A majority of youths aged 12 to 17 reported that they disapprove of their peers using substances. In 2011, 91.0 percent of youths "strongly" or "somewhat" disapproved of their peers smoking one or more packs of cigarettes per day, which was similar to the rate of 90.5 percent in 2010, but was higher than the 87.1 percent in 2002. Also in 2011, 80.3 percent strongly or somewhat disapproved of peers using marijuana or hashish once a month or more, which was lower than the 81.5 percent reported in 2010, but was similar to the 80.4 percent reported in 2002. In addition, 88.1 percent of youths strongly or somewhat disapproved of peers having one or two drinks of an alcoholic beverage nearly every day in 2011, which was the same as the rate reported in 2010, but was higher than the 84.7 percent reported in 2002.

- In 2011, past month marijuana use was reported by 2.5 percent of youths aged 12 to 17 who strongly or somewhat disapproved of their peers using marijuana once a month or more, which was lower than the 29.9 percent among youths who reported that they neither approve nor disapprove of such behavior from their peers.

Fighting and Delinquent Behavior

- In 2011, 19.1 percent of youths aged 12 to 17 reported that, in the past year, they had gotten into a serious fight at school or at work; this was lower than the rates in 2010 (20.1 percent) and 2002 (20.6 percent). Approximately one in eight youths (12.2 percent) in 2011 had taken part in a group-against-group fight, which was similar to the rate in 2010 (12.8 percent) and was lower than the rate in 2002 (15.9 percent). About 1 in 30 (3.5 percent) had carried a handgun at least once in the past year in 2011, which was similar to the rates in 2010 (3.1 percent) and 2002 (3.3 percent). An estimated 5.9 percent had, in at least one instance, attacked others with the intent to harm or seriously hurt them in 2011, which was lower than the rates in 2010 (7.2 percent) and 2002 (7.8 percent). An estimated 3.0 percent had sold illegal drugs in 2011, which was similar to the rate of 3.1 percent in 2010, but was lower than the rate in 2002 (4.4 percent). In 2011, 3.8 percent had, at least once, stolen or tried to steal something worth more than \$50; this was similar to the rate of 4.0 percent in 2010, but was lower than the rate of 4.9 percent in 2002.
- Youths aged 12 to 17 who had engaged in fighting or other delinquent behaviors were more likely than other youths to have used illicit drugs in the past month. For instance, in 2011, past month illicit drug use was reported by 18.5 percent of youths who had gotten into a serious fight at school or work in the past year compared with 8.0 percent of those who had not engaged in fighting at school or work, and by 45.1 percent of those who had stolen or tried to steal something worth over \$50 in the past year compared with 8.7 percent of those who had not attempted or engaged in such theft.

Religious Beliefs and Participation in Activities

- In 2011, 30.7 percent of youths aged 12 to 17 reported that they had attended religious services 25 or more times in the past year, which was similar to the rate in 2010 (30.8 percent), but was lower than the rate in 2002 (33.0 percent). Also, 73.5 percent agreed or strongly agreed with the statement that religious beliefs are a very important part of their lives, which was similar to the rate in 2010 (74.6 percent), but was lower than the 78.2 percent reported in 2002. In 2011, 33.1 percent agreed or strongly agreed with the statement that it is important for their friends to share their religious beliefs, which was similar to the rate in 2010 (32.8 percent), but was lower than the rate in 2002 (35.8 percent).
- The rates of past month use of illicit drugs and cigarettes and binge alcohol use were lower among youths aged 12 to 17 who agreed with these statements about religious beliefs than among those who disagreed. For instance, in 2011, past month illicit drug use was reported by 7.4 percent of those who agreed or strongly agreed that religious beliefs are a very important part of their lives compared with 17.5 percent of those who disagreed with that statement. Similar differences were found between those two subgroups for the past month use of cigarettes and binge alcohol use (5.3 vs. 14.3 percent, and 5.7 and 12.1 percent, respectively).

Exposure to Substance Use Prevention Messages and Programs

- In 2011, approximately one in eight youths aged 12 to 17 (11.7 percent) reported that they had participated in drug, tobacco, or alcohol prevention programs outside of school in the past year. This rate was similar to the 11.5 percent reported in 2010, but was lower than the rate reported in 2002 (12.7 percent). In 2011, the prevalence of past month use did not differ significantly between those who did or did not participate in these programs for illicit drugs (10.8 and 9.9 percent, respectively), marijuana (7.5 and 7.9 percent), cigarettes (6.8 and 7.8 percent), or binge alcohol use (6.9 and 7.5 percent).
- In 2011, 75.1 percent of youths aged 12 to 17 reported having seen or heard drug or alcohol prevention messages in the past year from sources outside of school, which was similar to the 75.9 percent reported in 2010, but was lower than the 83.2 percent reported in 2002 (Figure 6.6). In 2011, the prevalence of past month use of illicit drugs among those who reported having such exposure (10.0 percent) was not significantly different from the prevalence among those who reported having no such exposure (10.2 percent).

Figure 6.6 Exposure to Substance Use Prevention Messages and Programs among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

¹ Estimates are from youths aged 12 to 17 who were enrolled in school in the past year.

- In 2011, 74.6 percent of youths aged 12 to 17 enrolled in school in the past year reported having seen or heard drug or alcohol prevention messages at school, which was similar to the 75.7 percent reported in 2010, but was lower than the 78.8 percent reported in 2002 (Figure 6.6). In 2011, the prevalence of past month use of illicit drugs or marijuana was lower among those who reported having such exposure (9.2 and 7.2 percent for illicit drugs and marijuana, respectively) than among those who reported having no such exposure (13.2 and 10.8 percent).

Parental Involvement

- Youths aged 12 to 17 were asked several questions related to the extent of support, oversight, and control that they perceived their parents exercised over them in the year prior to the survey interview. In 2011, among youths aged 12 to 17 who were enrolled in school in the past year, 69.9 percent reported that their parents limited the amount of time that they spent out with friends on school nights. This was similar to the rate reported in 2010 and remained statistically unchanged from the rate reported in 2002. In 2011, 81.1 percent reported that in the past year their parents always or sometimes checked on whether or not they had completed their homework, and 80.4 percent reported that their parents always or sometimes provided help with their homework. Both of the rates reported in 2011 were similar to the rates in 2010. However, the rate for parents checking on completing homework was higher than in 2002 (78.4 percent), and the rate for parents providing help with homework was lower than the rate in 2002 (81.4 percent).
- In 2011, 88.4 percent of youths aged 12 to 17 reported that in the past year their parents always or sometimes made them do chores around the house, which was similar to the rate in 2010 (88.0 percent), but was slightly higher than the rate in 2002 (87.4 percent). In 2011, 85.9 percent of youths reported that their parents always or sometimes let them know that they had done a good job, and 85.8 percent reported that their parents always or sometimes let them know they were proud of something they had done. These percentages in 2011 were similar to those reported in 2010 and 2002. In 2011, 40.5 percent of youths reported that their parents limited the amount of time that they watched television, which was similar to the rate in 2010 (39.5 percent), but was higher than the 36.9 percent reported in 2002.
- In 2011, past month use of illicit drugs and cigarettes and binge alcohol use were lower among youths aged 12 to 17 who reported that their parents always or sometimes engaged in monitoring behaviors than among youths whose parents seldom or never engaged in such behaviors. For instance, the rate of past month use of any illicit drug was 8.2 percent for youths whose parents always or sometimes helped with homework compared with 18.7 percent among youths who indicated that their parents seldom or never helped. Rates of current cigarette smoking and past month binge alcohol use also were lower among youths whose parents always or sometimes helped with homework (6.3 and 6.1 percent, respectively) than among youths whose parents seldom or never helped (14.3 and 13.8 percent).

7. Substance Dependence, Abuse, and Treatment

The National Survey on Drug Use and Health (NSDUH) includes a series of questions to assess the prevalence of substance use disorders (substance dependence or abuse) in the past 12 months. Substances include alcohol and illicit drugs, such as marijuana, cocaine, heroin, hallucinogens, inhalants, and the nonmedical use of prescription-type psychotherapeutic drugs. These questions are used to classify persons as dependent on or abusing specific substances based on criteria specified in the *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition (DSM-IV) (American Psychiatric Association [APA], 1994).

The questions related to dependence ask about health and emotional problems associated with substance use, unsuccessful attempts to cut down on use, tolerance, withdrawal, reducing other activities to use substances, spending a lot of time engaging in activities related to substance use, or using the substance in greater quantities or for a longer time than intended. The questions on abuse ask about problems at work, home, and school; problems with family or friends; physical danger; and trouble with the law due to substance use. Dependence is considered to be a more severe substance use problem than abuse because it involves the psychological and physiological effects of tolerance and withdrawal.

This chapter provides estimates of the prevalence and patterns of substance use disorders occurring in the past year from the 2011 NSDUH and compares these estimates against the results from the 2002 through 2010 surveys. It also provides estimates of the prevalence and patterns of the receipt of treatment in the past year for problems related to substance use. This chapter concludes with a discussion of the need for and the receipt of treatment at specialty facilities for problems associated with substance use.

7.1. Substance Dependence or Abuse

- In 2011, an estimated 20.6 million persons aged 12 or older were classified with substance dependence or abuse in the past year (8.0 percent of the population aged 12 or older) (Figure 7.1). Of these, 2.6 million were classified with dependence or abuse of both alcohol and illicit drugs, 3.9 million had dependence or abuse of illicit drugs but not alcohol, and 14.1 million had dependence or abuse of alcohol but not illicit drugs.
- The annual number of persons with substance dependence or abuse remained stable between 2002 and 2010, ranging from 21.6 million to 22.7 million. However, the number in 2011 (20.6 million) was lower than the number in 2010 (22.2 million).
- In 2011, 16.7 million persons aged 12 or older were classified with alcohol dependence or abuse, which was lower than the number in 2010 (18.0 million) and in each year from 2002 to 2009 (18.1 million in 2002, 17.8 million in 2003, 18.7 million in 2004, 18.7 million in 2005, 18.9 million in 2006, 18.7 million in 2007, 18.5 million in 2008, and 18.8 million in 2009).

Figure 7.1 Substance Dependence or Abuse in the Past Year among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

- In 2011, 6.5 percent of the population aged 12 or older had alcohol dependence or abuse, which was lower than the rate in each year since 2002 (7.7 percent in 2002, 7.5 percent in 2003, 7.8 percent in 2004, 7.7 percent in 2005, 7.7 percent in 2006, 7.5 percent in 2007, 7.4 percent in 2008, 7.5 percent in 2009, and 7.1 percent in 2010).
- The number of persons aged 12 or older who had illicit drug dependence or abuse was similar between 2010 (7.1 million) and 2011 (6.5 million) and between 2002 (7.1 million) and 2011. However, the rate of persons aged 12 or older who had illicit drug dependence or abuse in 2011 (2.5 percent) was lower than the rate in 2010 (2.8 percent) and in most years from 2002 to 2009. The rate of illicit drug dependence or abuse in 2002 to 2009 ranged from 2.8 to 3.0 percent.
- Marijuana was the illicit drug with the highest rate of past year dependence or abuse in 2011, followed by pain relievers and cocaine. Of the 6.5 million persons aged 12 or older classified with illicit drug dependence or abuse in 2011, 4.2 million had marijuana dependence or abuse (representing 1.6 percent of the total population aged 12 or older, and 63.8 percent of all those classified with illicit drug dependence or abuse), 1.8 million persons had pain reliever dependence or abuse, and 821,000 persons had cocaine dependence or abuse (Figure 7.2).

Figure 7.2 Specific Illicit Drug Dependence or Abuse in the Past Year among Persons Aged 12 or Older: 2011

- The number of persons who had marijuana dependence or abuse did not change significantly between 2002 (4.3 million) and 2011 (4.2 million) or between 2010 (4.5 million) and 2011 (Figure 7.3). The rate of persons who had marijuana dependence or abuse in 2011 (1.6 percent) was lower than the rates in 2002 (1.8 percent) and 2004 (1.9 percent), but was similar to the rate in 2010 (1.8 percent).
- The rate and the number of persons who had pain reliever dependence or abuse remained unchanged between 2010 (0.8 percent and 1.9 million) and 2011 (0.7 percent and 1.8 million) and between 2002 (0.6 percent and 1.5 million) and 2011. However, the number with pain reliever dependence or abuse was higher in 2011 than in 2004 (1.4 million).
- The rate and the number of persons who had cocaine dependence or abuse were similar between 2010 (0.4 percent and 1.0 million) and 2011 (0.3 percent and 821,000). However, they decreased between 2006 (0.7 percent and 1.7 million) and 2011.
- The rate and the number of persons who had heroin dependence or abuse were stable between 2010 (0.1 percent and 361,000) and 2011 (0.2 percent and 426,000). However, they increased between 2007 (0.1 percent and 214,000) and 2011.

Figure 7.3 Illicit Drug Dependence or Abuse in the Past Year among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Age at First Use

- In 2011, among adults aged 18 or older, age at first use of marijuana was associated with illicit drug dependence or abuse. Among those who first tried marijuana at age 14 or younger, 12.7 percent were classified with illicit drug dependence or abuse, which was higher than the 2.0 percent of adults who had first used marijuana at age 18 or older.
- Among adults, age at first use of alcohol was associated with alcohol dependence or abuse. In 2011, among adults aged 18 or older who first tried alcohol at age 14 or younger, 14.8 percent were classified with alcohol dependence or abuse, which was higher than the 3.5 percent of adults who had first used alcohol at age 18 or older. Adults aged 21 or older who had first used alcohol before age 21 were more likely than adults who had their first drink at age 21 or older to be classified with alcohol dependence or abuse (Figure 7.4). In particular, adults aged 21 or older who had first used alcohol at age 14 or younger were more than 7 times as likely to be classified with alcohol dependence or abuse than adults who had their first drink at age 21 or older (13.8 vs. 1.8 percent). The rate of adults aged 21 or older who first used alcohol at age 21 or older and were classified with alcohol dependence or abuse in 2011 was lower than the rate in 2010 (2.7 percent).

Figure 7.4 Alcohol Dependence or Abuse in the Past Year among Adults Aged 21 or Older, by Age at First Use of Alcohol: 2011

Age

- Rates of substance dependence or abuse were associated with age. In 2011, the rate of substance dependence or abuse among adults aged 18 to 25 (18.6 percent) was higher than that among youths aged 12 to 17 (6.9 percent) and among adults aged 26 or older (6.3 percent). Both the rate among adults aged 18 to 25 and the rate among adults aged 26 or older declined between 2010 (20.0 and 7.0 percent, respectively) and 2011. From 2002 to 2011, the rate decreased for youths aged 12 to 17 (from 8.9 to 6.9 percent), for young adults aged 18 to 25 (from 21.7 to 18.6 percent), and for adults aged 26 or older (from 7.3 to 6.3 percent).
- The rate of alcohol dependence or abuse among youths aged 12 to 17 was 3.8 percent in 2011, which declined from 4.6 percent in 2010 and from 5.9 percent in 2002 (Figure 7.5). Among young adults aged 18 to 25, the rate of alcohol dependence or abuse also decreased between 2010 (15.7 percent) and 2011 (14.4 percent) and between 2002 (17.7 percent) and 2011. Among adults aged 26 or older, the rate was stable between 2010 (5.9 percent) and 2011 (5.4 percent), but it decreased between 2002 (6.2 percent) and 2011.

Figure 7.5 Alcohol and Illicit Drug Dependence or Abuse among Youths Aged 12 to 17: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Gender

- As was the case from 2002 through 2010, the rate of substance dependence or abuse for males aged 12 or older in 2011 was about twice as high as the rate for females. For males in 2011, the rate was 10.4 percent, which decreased from 11.7 percent in 2010 (Figure 7.6). For females, it was 5.7 percent in 2011, which did not differ from the rate of 6.0 percent in 2010. Among youths aged 12 to 17, the rate of substance dependence or abuse among males was not different from the rate among females in 2011 (6.9 percent for each).

Race/Ethnicity

- In 2011, among persons aged 12 or older, the rate of substance dependence or abuse was lower among Asians (3.3 percent) than among other racial/ethnic groups. The rates for the other racial/ethnic groups were 16.8 percent for American Indians or Alaska Natives, 10.6 percent for Native Hawaiians or Other Pacific Islanders, 9.0 percent for persons reporting two or more races, 8.7 percent for Hispanics, 8.2 percent for whites, and 7.2 percent for blacks.

Figure 7.6 Substance Dependence or Abuse in the Past Year, by Age and Gender: 2011

Education

- Rates of substance dependence or abuse were associated with level of education in 2011. Among adults aged 18 or older, those who graduated from a college or university had a lower rate of substance dependence or abuse (6.4 percent) than those who graduated from high school (8.0 percent), those who did not graduate from high school (9.3 percent), and those with some college (9.5 percent).

Employment

- Rates of substance dependence or abuse were associated with current employment status in 2011. A higher percentage of unemployed adults aged 18 or older were classified with dependence or abuse (14.8 percent) than were full-time employed adults (8.4 percent) or part-time employed adults (9.8 percent).
- About half of the adults aged 18 or older with substance dependence or abuse were employed full time in 2011. Of the 18.9 million adults classified with dependence or abuse, 9.8 million (51.8 percent) were employed full time.

Criminal Justice Populations

- In 2011, adults aged 18 or older who were on parole or a supervised release from jail during the past year had higher rates of illicit drug or alcohol dependence or abuse (35.1 percent) than their counterparts who were not on parole or supervised release during the past year (7.9 percent).
- In 2011, probation status was associated with substance dependence or abuse. The rate of substance dependence or abuse was 33.7 percent among adults who were on probation during the past year, which was higher than the rate among adults who were not on probation during the past year (7.6 percent).

Geographic Area

- In 2011, rates of substance dependence or abuse for persons aged 12 or older were 8.9 percent in the West, 8.6 percent in the Northeast, 8.3 percent in the Midwest, and 7.0 percent in the South.
- Rates for substance dependence or abuse among persons aged 12 or older in 2011 were similar in large metropolitan counties (8.4 percent) and small metropolitan counties (8.2 percent), but were higher than in nonmetropolitan counties (6.3 percent).

7.2. Past Year Treatment for a Substance Use Problem

Estimates described in this section refer to treatment received for illicit drug or alcohol use, or for medical problems associated with the use of illicit drugs or alcohol. This includes treatment received in the past year at any location, such as a hospital (inpatient), rehabilitation facility (outpatient or inpatient), mental health center, emergency room, private doctor's office, prison or jail, or a self-help group, such as Alcoholics Anonymous or Narcotics Anonymous. Persons could report receiving treatment at more than one location. Note that the definition of treatment in this section is different from the definition of specialty treatment described in Section 7.3. Specialty treatment includes treatment only at a hospital (inpatient), a rehabilitation facility (inpatient or outpatient), or a mental health center.

Individuals who reported receiving substance use treatment but were missing information on whether the treatment was specifically for alcohol use or illicit drug use were not counted in estimates of either illicit drug use treatment or alcohol use treatment; however, they were counted in estimates for "drug or alcohol use" treatment.

- In 2011, 3.8 million persons aged 12 or older (1.5 percent of the population) received treatment for a problem related to the use of alcohol or illicit drugs. Of these, 1.2 million received treatment for the use of both alcohol and illicit drugs, 0.8 million received treatment for the use of illicit drugs but not alcohol, and 1.4 million received treatment for the use of alcohol but not illicit drugs. (Note that estimates by substance do not sum to the total number of persons receiving treatment because the total includes persons who reported receiving treatment but did not report for which substance the treatment was received.)

- The rate and the number of persons in the population aged 12 or older receiving substance use treatment within the past year was stable between 2010 (1.6 percent and 4.2 million) and 2011 (1.5 percent and 3.8 million) and between 2002 (1.5 percent and 3.5 million) and 2011.
- In 2011, among the 3.8 million persons aged 12 or older who received treatment for alcohol or illicit drug use in the past year, 2.1 million persons received treatment at a self-help group, and 1.5 million received treatment at a rehabilitation facility as an outpatient (Figure 7.7). There were 1.0 million persons who received treatment at a mental health center as an outpatient, 1.0 million persons who received treatment at a rehabilitation facility as an inpatient, 871,000 at a hospital as an inpatient, 700,000 at a private doctor's office, 574,000 at an emergency room, and 435,000 at a prison or jail. None of these estimates changed significantly between 2010 and 2011. Except for persons who received treatment at a prison or jail, these estimates also did not change between 2002 and 2011; the number of persons who received treatment at a prison or jail increased from 259,000 in 2002 to 435,000 in 2011.

Figure 7.7 Locations Where Past Year Substance Use Treatment Was Received among Persons Aged 12 or Older: 2011

- In 2011, during their most recent treatment in the past year, 2.4 million persons aged 12 or older reported receiving treatment for alcohol use, and 872,000 persons reported receiving treatment for marijuana use (Figure 7.8). Estimates for receiving treatment for the use of other drugs were 726,000 persons for pain relievers, 511,000 for cocaine, 430,000 for heroin, 318,000 for tranquilizers, 309,000 for stimulants, and 293,000 for hallucinogens. None of these estimates changed significantly between 2010 and 2011.

Figure 7.8 Substances for Which Most Recent Treatment Was Received in the Past Year among Persons Aged 12 or Older: 2011

- The numbers of persons aged 12 or older who received treatment for the use of pain relievers (see Figure 7.9) and tranquilizers increased between 2002 and 2011. Numbers who received treatment for pain relievers in 2009 to 2011 ranged from 726,000 to 761,000 persons and were greater than the numbers in 2002 to 2005.
- The numbers of persons aged 12 or older who received treatment for marijuana, hallucinogens, and stimulants were stable between 2002 and 2011. (Note that respondents could indicate that they received treatment for more than one substance during their most recent treatment.)

Figure 7.9 Received Most Recent Treatment in the Past Year for the Use of Pain Relievers among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

7.3. Need for and Receipt of Specialty Treatment

This section discusses the need for and receipt of treatment for a substance use problem at a "specialty" treatment facility. Specialty treatment is defined as treatment received at any of the following types of facilities: hospitals (inpatient only), drug or alcohol rehabilitation facilities (inpatient or outpatient), or mental health centers. It does not include treatment at an emergency room, private doctor's office, self-help group, prison or jail, or hospital as an outpatient. An individual is defined as needing treatment for an alcohol or drug use problem if he or she met the DSM-IV (APA, 1994) diagnostic criteria for alcohol or illicit drug dependence or abuse in the past 12 months or if he or she received specialty treatment for alcohol use or illicit drug use in the past 12 months.

In this section, an individual needing treatment for an illicit drug use problem is defined as receiving treatment for his or her drug use problem only if he or she reported receiving specialty treatment for illicit drug use in the past year. Thus, an individual who needed treatment for illicit drug use but received specialty treatment only for alcohol use in the past year or who received treatment for illicit drug use only at a facility not classified as a specialty facility was not counted as receiving treatment for illicit drug use. Similarly, an individual who needed

treatment for an alcohol use problem was counted as receiving alcohol use treatment only if the treatment was received for alcohol use at a specialty treatment facility. Individuals who reported receiving specialty substance use treatment but were missing information on whether the treatment was specifically for alcohol use or drug use were not counted in estimates of specialty drug use treatment or in estimates of specialty alcohol use treatment; however, they were counted in estimates for "drug or alcohol use" treatment.

In addition to questions about symptoms of substance use problems that are used to classify respondents' need for treatment based on DSM-IV criteria, NSDUH includes questions asking respondents about their perceived need for treatment (i.e., whether they felt they needed treatment or counseling for illicit drug use or alcohol use). In this report, estimates for perceived need for treatment are discussed only for persons who were classified as needing treatment (based on DSM-IV criteria) but did not receive treatment at a specialty facility. Similarly, estimates for whether a person made an effort to get treatment are discussed only for persons who felt the need for treatment and did not receive it.

Illicit Drug or Alcohol Use Treatment and Treatment Need

- In 2011, 21.6 million persons aged 12 or older needed treatment for an illicit drug or alcohol use problem (8.4 percent of persons aged 12 or older). Both the rate and the number declined between 2010 (9.2 percent and 23.2 million) and 2011 and between 2002 (9.7 percent and 22.8 million) and 2011. In 2011, 2.3 million persons (0.9 percent of persons aged 12 or older and 10.8 percent of those who needed treatment) received treatment at a specialty facility, which did not differ from the rates and numbers in 2010 and 2002.
- In 2011, 19.3 million persons (7.5 percent of the population aged 12 or older) needed treatment for an illicit drug or alcohol use problem but did not receive treatment at a specialty facility in the past year. Both the rate and the number declined between 2010 (8.1 percent and 20.6 million) and 2011 and between 2002 (8.7 percent and 20.5 million) and 2011.
- Of the 2.3 million persons aged 12 or older who received specialty substance use treatment in 2011, 898,000 received treatment for alcohol use only, 780,000 received treatment for illicit drug use only, and 574,000 received treatment for both alcohol and illicit drug use. These estimates were similar to the estimates for 2010 and 2002.
- Among persons in 2011 who received their most recent substance use treatment at a specialty facility in the past year, 46.4 percent reported using their "own savings or earnings" as a source of payment for their most recent specialty treatment, 38.5 percent reported using private health insurance, 35.0 percent reported using Medicaid, 31.2 percent reported using Medicare, 31.0 percent reported using public assistance other than Medicaid, and 26.0 percent reported using funds from family members. None of these estimates changed significantly between 2010 and 2011. However, there were increases in persons reporting using Medicaid or using Medicare between 2002 (23.1 and 19.5 percent, respectively) and 2011.

- Of the 19.3 million persons aged 12 or older in 2011 who were classified as needing substance use treatment but not receiving treatment at a specialty facility in the past year, 912,000 persons (4.7 percent) reported that they perceived a need for treatment for their illicit drug or alcohol use problem (Figure 7.10). Of these 912,000 persons who felt they needed treatment but did not receive treatment in 2011, 281,000 (30.8 percent) reported that they made an effort to get treatment, and 631,000 (69.2 percent) reported making no effort to get treatment. These estimates were stable between 2010 and 2011.
- The rate and the number of youths aged 12 to 17 who needed treatment for an illicit drug or alcohol use problem in 2011 (7.0 percent and 1.7 million) were similar to those in 2010 (7.5 percent and 1.8 million), but they were lower than those in 2002 (9.1 percent and 2.3 million). Of the 1.7 million youths who needed treatment in 2011, 146,000 received treatment at a specialty facility (about 8.4 percent of the youths who needed treatment), leaving about 1.6 million who needed treatment for a substance use problem but did not receive it at a specialty facility.

Figure 7.10 Past Year Perceived Need for and Effort Made to Receive Specialty Treatment among Persons Aged 12 or Older Needing But Not Receiving Treatment for Illicit Drug or Alcohol Use: 2011

19.3 Million Needing But Not Receiving Treatment for Illicit Drug or Alcohol Use

Note: The percentages do not add to 100 percent due to rounding.

- Based on 2008-2011 combined data, the six most often reported reasons for not receiving illicit drug or alcohol use treatment among persons aged 12 or older who needed and perceived a need for treatment but did not receive treatment at a specialty facility were (a) not ready to stop using (39.2 percent), (b) no health coverage and could not afford cost (32.3 percent), (c) possible negative effect on job (13.9 percent), (d) concern that receiving treatment might cause neighbors/community to have negative opinion (12.3 percent), (e) not knowing where to go for treatment (9.9 percent), and (f) could handle the problem without treatment (8.8 percent).
- Based on 2008-2011 combined data, among persons aged 12 or older who needed but did not receive illicit drug or alcohol use treatment, felt a need for treatment, and made an effort to receive treatment, the most often reported reasons for not receiving treatment were (a) no health coverage and could not afford cost (37.3 percent), (b) not ready to stop using (25.5 percent), (c) might have negative effect on job (10.1 percent), (d) had health coverage but did not cover treatment or did not cover cost (10.1 percent), (e) no transportation or inconvenient (9.5 percent), (f) did not know where to go for treatment (7.3 percent), (g) might cause neighbors/community to have negative opinion (7.2 percent), and (h) did not have time for treatment (7.1 percent) (Figure 7.11).

Illicit Drug Use Treatment and Treatment Need

- In 2011, the number of persons aged 12 or older needing treatment for an illicit drug use problem was 7.2 million (2.8 percent of the total population). Both the rate and the number declined between 2010 (3.1 percent and 7.9 million) and 2011. Although the percentage of persons needing treatment for an illicit drug use problem declined between 2002 (3.3 percent) and 2011, the corresponding number of persons did not differ between 2002 (7.7 million) and 2011.
- Of the 7.2 million persons aged 12 or older who needed treatment for an illicit drug use problem in 2011, 1.4 million (0.5 percent of the total population and 18.8 percent of persons who needed treatment) received treatment at a specialty facility for an illicit drug use problem in the past year. The rate and the number were similar between 2010 and 2011 and between 2002 and 2011.
- There were 5.8 million persons (2.3 percent of the total population) who needed but did not receive treatment at a specialty facility for an illicit drug use problem in 2011, which declined between 2010 (6.4 million and 2.5 percent) and 2011. The rate declined between 2002 (2.7 percent) and 2011, but the numbers in 2002 (6.3 million) and 2011 were similar.
- Of the 5.8 million people aged 12 or older who needed but did not receive specialty treatment for illicit drug use in 2011, 488,000 (8.4 percent) reported that they perceived a need for treatment for their illicit drug use problem, and 5.3 million did not perceive a need for treatment. The number of persons who needed treatment for an illicit drug use problem but did not perceive the need declined between 2010 (6.0 million) and 2011 (5.3 million).

Figure 7.11 Reasons for Not Receiving Substance Use Treatment among Persons Aged 12 or Older Who Needed and Made an Effort to Get Treatment But Did Not Receive Treatment and Felt They Needed Treatment: 2008-2011 Combined

- Of the 488,000 persons who felt a need for treatment in 2011, 187,000 reported that they made an effort to get treatment, and 301,000 reported making no effort to get treatment. These estimates were similar to the estimates in 2010.
- Among youths aged 12 to 17, there were 1.2 million persons (4.7 percent) who needed treatment for an illicit drug use problem in 2011. Of this group, only 125,000 received treatment at a specialty facility (10.5 percent of youths aged 12 to 17 who needed treatment), leaving 1.1 million youths who needed treatment but did not receive it at a specialty facility.

- Among people aged 12 or older who needed but did not receive illicit drug use treatment and felt they needed treatment (based on 2008-2011 combined data), the most often reported reasons for not receiving treatment were (a) no health coverage and could not afford cost (43.6 percent), (b) not ready to stop using (29.0 percent), (c) concern that receiving treatment might cause neighbors/community to have negative opinion (14.6 percent), (d) possible negative effect on job (14.1 percent), (e) not knowing where to go for treatment (14.0 percent), and (f) having health coverage that did not cover treatment (10.6 percent).

Alcohol Use Treatment and Treatment Need

- In 2011, the number of persons aged 12 or older needing treatment for an alcohol use problem was 17.4 million (6.8 percent of the population aged 12 or older). Both the number and the rate declined between 2010 (18.6 million and 7.3 percent) and 2011 and between 2002 (18.6 million and 7.9 percent) and 2011.
- Among the 17.4 million persons aged 12 or older who needed treatment for an alcohol use problem in 2011, 1.5 million (0.6 percent of the total population and 8.5 percent of the people who needed treatment for an alcohol use problem) received alcohol use treatment at a specialty facility. These estimates of the need and receipt of treatment for an alcohol use problem did not change significantly between 2010 and 2011 or between 2002 and 2011. However, the number and the rate of persons aged 12 or older who needed but did not receive treatment at a specialty facility for an alcohol use problem declined between 2010 (17.0 million and 6.7 percent) and 2011 (16.0 million and 6.2 percent) and between 2002 (17.1 million and 7.3 percent) and 2011.
- Among the 16.0 million people aged 12 or older who needed but did not receive specialty treatment for an alcohol use problem in 2011, there were 505,000 persons (3.2 percent) who felt they needed treatment for their alcohol use problem. The number and the rate were similar to those reported in 2010 (706,000 persons and 4.1 percent), but were lower than those reported in 2002 (761,000 persons and 4.5 percent). Of the 505,000 persons in 2011 who perceived a need for treatment for an alcohol use problem but did not receive specialty treatment, 368,000 did not make an effort to get treatment, and 137,000 made an effort but were unable to get treatment in 2011.
- In 2011, there were 978,000 youths aged 12 to 17 (3.9 percent) who needed treatment for an alcohol use problem. Of this group, only 63,000 received treatment at a specialty facility (0.3 percent of all youths and 6.4 percent of youths who needed treatment), leaving about 915,000 youths (3.7 percent) who needed but did not receive treatment.

8. Discussion of Trends in Marijuana, Prescription Drug, Heroin, and Other Substance Use among Youths and Young Adults

Previous chapters in this report presented findings from the 2011 National Survey on Drug Use and Health (NSDUH) that describe trends and demographic differences for the incidence and prevalence of use for a variety of substances. This chapter expands upon previous chapters by discussing, in more depth, topics that have been of particular interest in recent years. That is, a comparison of NSDUH trend results with results from other surveys of youth and young adult substance use is presented. Recent trends in the misuse of prescription pain relievers and in the use of heroin, based on NSDUH and other data sources, are discussed.

Description of NSDUH and Other Data Sources

Conducted since 1971 and previously named the National Household Survey on Drug Abuse (NHSDA), the survey underwent several methodological improvements in 2002 that have affected prevalence estimates. As a result, the 2002 through 2011 estimates are not comparable with estimates from 2001 and earlier surveys. Therefore, the primary focus of this report is on comparisons of measures of substance use across subgroups of the U.S. population in 2011, changes between 2010 and 2011, and changes between 2002 and 2011. An important step in the analysis and interpretation of NSDUH or any other survey data is to compare the results with those from other data sources. This can be difficult because the other surveys typically have different purposes, definitions, and designs. Research has established that surveys of substance use and other sensitive topics often produce inconsistent results because of different methods used. Thus, it is important to understand that conflicting results often reflect differing methodologies, not incorrect results. Despite this limitation, comparisons can be very useful. Consistency across surveys can confirm or support conclusions about trends and patterns of use, and inconsistent results can point to areas for further study. Further discussion of this issue is included in Appendix C, along with descriptions of methods and results from other sources of substance use data.

Unfortunately, few additional data sources are available to compare with NSDUH results. One established source is Monitoring the Future (MTF), a study sponsored by the National Institute on Drug Abuse (NIDA). MTF surveys students in the 8th, 10th, and 12th grades in classrooms during the spring of each year, and it also collects data by mail from a subsample of adults who had participated earlier in the study as 12th graders (Johnston, O'Malley, Bachman, & Schulenberg, 2011, 2012). Historically, NSDUH rates of youth substance use have been lower than those of MTF. Occasionally, the two surveys have shown different trends in youth substance use over a short time period, although the two sources of youth behavior have shown very similar long-term trends in prevalence. NSDUH and MTF rates of substance use generally have been similar among young adults, and the two sources also have shown similar trends.

Another source of data on trends in the use of drugs among youths is the Youth Risk Behavior Survey (YRBS), sponsored by the Centers for Disease Control and Prevention (CDC). YRBS surveys students in the 9th through 12th grades in classrooms every other year during the spring (Eaton et al., 2012). The most recent survey was completed in 2011. Generally, the YRBS showed higher prevalence rates but similar trends when compared with NSDUH and MTF. However, comparisons between the YRBS and NSDUH or MTF were less straightforward because of the different periodicity (i.e., biennially instead of annually) and ages covered, the limited number of drug use questions, and smaller sample size in the YRBS.

For the pain reliever and heroin analyses, data from two other studies are discussed. The Treatment Episode Data Set (TEDS) is a SAMHSA study that compiles data on admissions to publicly funded substance abuse treatment centers in the United States. The Drug Abuse Warning Network (DAWN) is a SAMHSA public health surveillance system that, since 2004, has monitored a nationally representative sample of hospitals in the United States for patients' medical records of emergency department visits that are related to drug use, abuse, and misuse.

Comparison of NSDUH, MTF, and YRBS Trends

A comparison of NSDUH and MTF estimates for 2002 to 2011 is shown in Tables 8.1 through 8.6 at the end of this chapter for several substances that are defined similarly in the two surveys. For comparison purposes, MTF data on 8th and 10th graders are combined to give an age range close to 12 to 17 years, the standard youth age group for NSDUH. Appendix C provides comparisons according to MTF definitions. MTF follow-up data on persons aged 19 to 24 provide the closest match on age to estimates for NSDUH young adults aged 18 to 25. The NSDUH results are remarkably consistent with MTF trends for both youths and young adults, as discussed in the following paragraphs.

Both surveys showed decreases between 2002 and 2011 in the percentages of youths who used cocaine, inhalants, alcohol, and cigarettes in the past month (Table 8.3). For youth alcohol use, MTF showed a decrease between 2010 and 2011, while NSDUH indicated no significant change. Over the long term, however, the two surveys have shown remarkably consistent trends in alcohol use (Figure 8.1). There have been other instances where the two surveys show differing trends from 1 year to the next, but these discrepancies usually "correct" themselves with 1 or 2 more years of data, pointing to the need to use caution in the interpretation of 1-year shifts in prevalence levels.² For marijuana use, both surveys showed declines from 2002 to 2006 and increases from 2008 to 2011, with the 2011 estimates approaching the respective 2002 levels (Figure 8.3). NSDUH and MTF data showed generally consistent trends for past month use of Ecstasy, with decreases in use from 2002 to the middle of the decade, then increasing use from 2007 to 2010. However, MTF showed a decline in use in 2011, while NSDUH did not. Both surveys indicated little change in past month use of LSD.

² For example, 2010 MTF data indicated a leveling or possible increase in current cigarette use among youths, in contrast to the 2010 NSDUH data, which showed a continuing decline. The 2011 MTF estimate, however, was lower than the 2010 estimate, and over the long term, the two surveys showed consistent trends. From 2006 to 2011, NSDUH and MTF each showed a 2.6 percentage point decline in youth cigarette use (Figure 8.2).

Figure 8.1 Past Month Alcohol Use among Youths in NSDUH and MTF: 2002-2011

MTF = Monitoring the Future; NSDUH = National Survey on Drug Use and Health.

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

MTF = Monitoring the Future; NSDUH = National Survey on Drug Use and Health.

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

NSDUH and MTF also collect data on perceived risk of harm. The extent to which youths believe that substances might cause them harm is an important factor influencing whether or not they will use these substances. Declining levels of perceived risk among youths historically have been associated with subsequent increases in rates of use. Among youths aged 12 to 17, the percentage reporting in NSDUH that they thought there was a great risk of harm in smoking marijuana once or twice a week declined from 54.6 percent in 2007 to 44.8 percent in 2011. MTF data for combined 8th and 10th graders showed a similar decline in perceived great risk of harm of regular marijuana use over this time period, from 69.4 to 61.8 percent.

For the substances for which information on current use was collected in the YRBS, including alcohol, cigarettes, marijuana, and cocaine, the YRBS trend results between 2001 and 2011 were consistent with NSDUH and MTF (see <http://www.cdc.gov/HealthyYouth/yrebs/>; Grunbaum et al., 2002). YRBS data for the combined grades 9 through 12 showed decreases in past month alcohol use (47.1 percent in 2001 and 38.7 percent in 2011) and cigarette use (28.5 percent in 2001 and 18.1 percent in 2011). YRBS showed a decline in past month marijuana use between 2001 (23.9 percent) and 2007 (19.7 percent), and an increase between 2007 and 2011 (23.1 percent). This increase was consistent with the recent NSDUH and MTF increases since 2007.

Although changes in NSDUH survey methodology preclude direct comparisons of recent estimates with estimates from before 2002, it is important to put the recent trends in context by reviewing longer term trends in use. NSDUH data (prior to the design changes in 1999 and 2002) on youths aged 12 to 17 and MTF data on high school seniors showed substantial increases in youth illicit drug use during the 1970s, reaching a peak in the late 1970s. Both surveys then showed declines throughout the 1980s until about 1992, when rates reached a low point. These trends were driven by the trend in marijuana use. With the start of annual data collection in NSDUH in 1991, along with the biennial YRBS and the annual 8th and 10th grade samples in MTF, trends among youths are well documented since the low point that occurred in the early 1990s. Although they employ different survey designs and cover different age groups, the three surveys are consistent in showing increasing rates of marijuana use during the early to mid-1990s, reaching a peak in the late 1990s (but lower than in the late 1970s). This peak in the late 1990s was followed by declines in use after the turn of the 21st century and an increase in the most recent years (Figure 8.4).

Figure 8.4 Past Month Marijuana Use among Youths in NSDUH, MTF, and YRBS: 1971-2011

MTF = Monitoring the Future; NSDUH = National Survey on Drug Use and Health; YRBS = Youth Risk Behavior Survey.

Note: NSDUH data for youths aged 12 to 17 are not presented for 1999 to 2001 because of design changes in the survey. These design changes preclude direct comparisons of estimates from 2002 to 2011 with estimates prior to 1999.

Data on young adults also showed similar trends in NSDUH and MTF, although not as consistent as for the youth data (Tables 8.4 to 8.6). Potential reasons for differences from the data for youths are the relatively smaller MTF sample size for young adults and possible bias in the MTF sample due to noncoverage of school dropouts and a low overall response rate; the response rate is affected by nonresponse by schools, by students in the 12th grade survey, and by students in the follow-up mail survey.

Both surveys showed an increase in past month marijuana use among young adults from 2008 to 2011 (16.6 to 19.0 percent in NSDUH; 17.3 to 20.1 percent in MTF) (Table 8.6). Both surveys showed declines in cigarette use between 2002 and 2011, with NSDUH showing a decline from 40.8 to 33.5 percent and MTF showing a decline from 31.4 to 21.3 percent. There was no significant change between 2002 and 2011 in the rate of current alcohol use among young adults in either survey. Both surveys showed declines in past year and past month cocaine use from 2002 to 2011, with no changes in rates between 2010 and 2011 (Tables 8.5 and 8.6, respectively). Similarly, past year and past month Ecstasy use among young adults increased between 2007 and 2010 and remained steady in 2011, according to both NSDUH and MTF.

Nonmedical Use of Prescription Pain Relievers

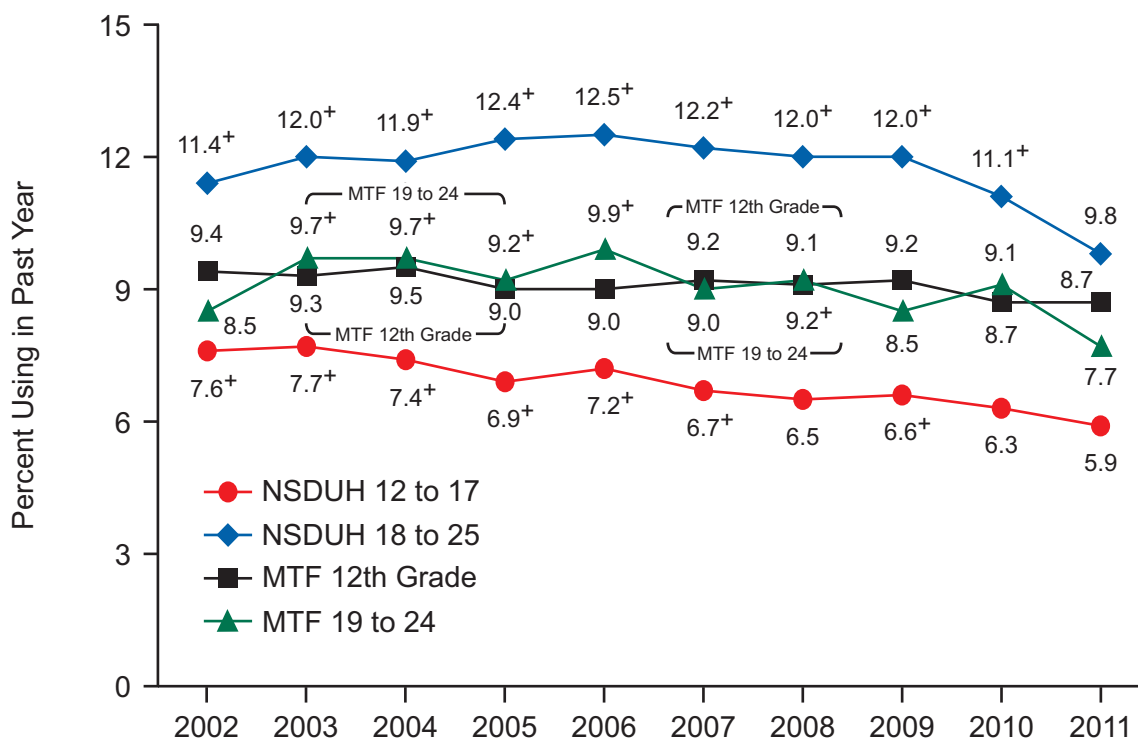

As noted in Chapter 2 of this report, NSDUH data indicated that nonmedical use of prescription drugs among youths aged 12 to 17 and young adults aged 18 to 25 in 2011 was the second most prevalent illicit drug use category, with marijuana being first. NSDUH data showed a decline in past month nonmedical prescription drug use among youths between 2002 (4.0 percent) and 2008 (2.9 percent), with no significant change between 2008 and 2011 (2.8 percent). Among young adults aged 18 to 25, past month prevalence of nonmedical prescription drug use was 5.0 percent in 2011. This prevalence in 2011 was lower than the rates in other years since 2003, which varied between 5.9 and 6.5 percent. The most prevalent category of misused prescription drugs is pain relievers. Nonmedical pain reliever use in the past month among youths declined from 3.2 percent in 2002 to 2.3 percent in 2011, while the rate among young adults was lower in 2011 (3.6 percent) than in 2010 (4.4 percent) as well as in years from 2002 to 2009 (between 4.1 and 5.0 percent).

NSDUH and MTF use different definitions and questioning strategies to track misuse of prescription drugs. For example, NSDUH defines misuse as use of prescription drugs that were not prescribed for the respondent or use of these drugs only for the experience or feeling they caused; MTF defines misuse as use not under a doctor's orders. MTF also does not estimate overall prescription drug misuse. However, MTF asks questions about "narcotics other than heroin," a category similar in coverage to the pain reliever category in NSDUH. These data are reported for 12th graders and for young adults. In addition, as is the case with NSDUH trends, methodological changes in MTF have sometimes resulted in discontinuities. For the data on use of narcotics other than heroin, there was a questionnaire change in the 2002 MTF that resulted in increased reporting of opiates, such that estimates prior to 2002 are not strictly comparable with estimates for 2002 and beyond.

Figure 8.5 shows NSDUH data for past year misuse of pain relievers from 2002 to 2011 for youths aged 12 to 17 and young adults aged 18 to 25 (comparable estimates for prior years are not available). MTF data for 12th graders and young adults (aged 19 to 24) are shown for

past year misuse of narcotics other than heroin since 2002. Except for 12th graders in MTF, both surveys showed declines from 2006 to 2011 in the prevalence of past year misuse of pain relievers/narcotics other than heroin. Among youths (NSDUH only), the rate of past year use declined from 7.2 to 5.9 percent. Among young adults, NSDUH showed a decline from 12.5 to 9.8 percent, while MTF showed a decline from 9.9 to 7.7 percent (Table 8.5). MTF estimates for 12th graders were similar between 2006 and 2011 (9.0 and 8.7 percent). However, the pattern of estimates for 12th graders in MTF between 2006 and 2011 was in the same direction as those for youths in NSDUH and young adults in both surveys.

Figure 8.5 Past Year Nonmedical Pain Reliever Use among Youths and Young Adults in NSDUH and MTF: 2002-2011

MTF = Monitoring the Future; NSDUH = National Survey on Drug Use and Health.

Note: Data for MTF are for "narcotics other than heroin."

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

Although the focus of attention is primarily on drug use among young people, NSDUH data demonstrate that the majority (57 percent) of past year nonmedical pain reliever users were aged 26 or older in 2011. Among this age group, the percentage that had used pain relievers nonmedically in the past 12 months rose from 3.1 percent in 2002 to 3.6 percent in 2006 and 2007, then declined to 3.2 percent in 2011.

These data generally indicate a decline in nonmedical pain reliever use from 2002 to 2011. However, other trends indicate a growing problem. According to NSDUH, initiation rates for nonmedical pain reliever use, although declining, were second to initiation rates for

marijuana in 2010 and 2011 and were similar to or greater than marijuana initiation rates in 2002 to 2009. There have been 1.9 million or more new nonmedical pain reliever users each year since 2002. The sustained numbers of new and continuing users have contributed to increases in indicators of problems associated with use, especially among adults. The number of persons with nonmedical pain reliever dependence increased from 936,000 in 2002 to 1.4 million in 2011. An estimated 56.1 percent of these pain reliever-dependent persons in 2011 were aged 26 or older, but about one third (472,000) were aged 18 to 25. As noted in Chapter 7, the number of persons receiving specialty substance use treatment within the past year for misuse of pain relievers increased during this period, from 199,000 to 438,000. In 2011, 63.7 percent of those receiving specialty substance abuse treatment for pain relievers were aged 26 or older, and 29.6 percent were aged 18 to 25. TEDS and DAWN data confirm these trends. Special analyses of TEDS admissions data indicate that admissions to publicly funded substance abuse treatment programs for a nonheroin opiate problem increased from 91,000 in 2002 to 259,000 in 2010; in 2010, 69 percent of such admissions were aged 25 or older, and 28 percent were aged 18 to 24. According to DAWN data, the number of emergency department visits involving nonmedical use of narcotic pain relievers increased from 145,000 in 2004 to 360,000 in 2010 (Center for Behavioral Health Statistics and Quality, 2012).

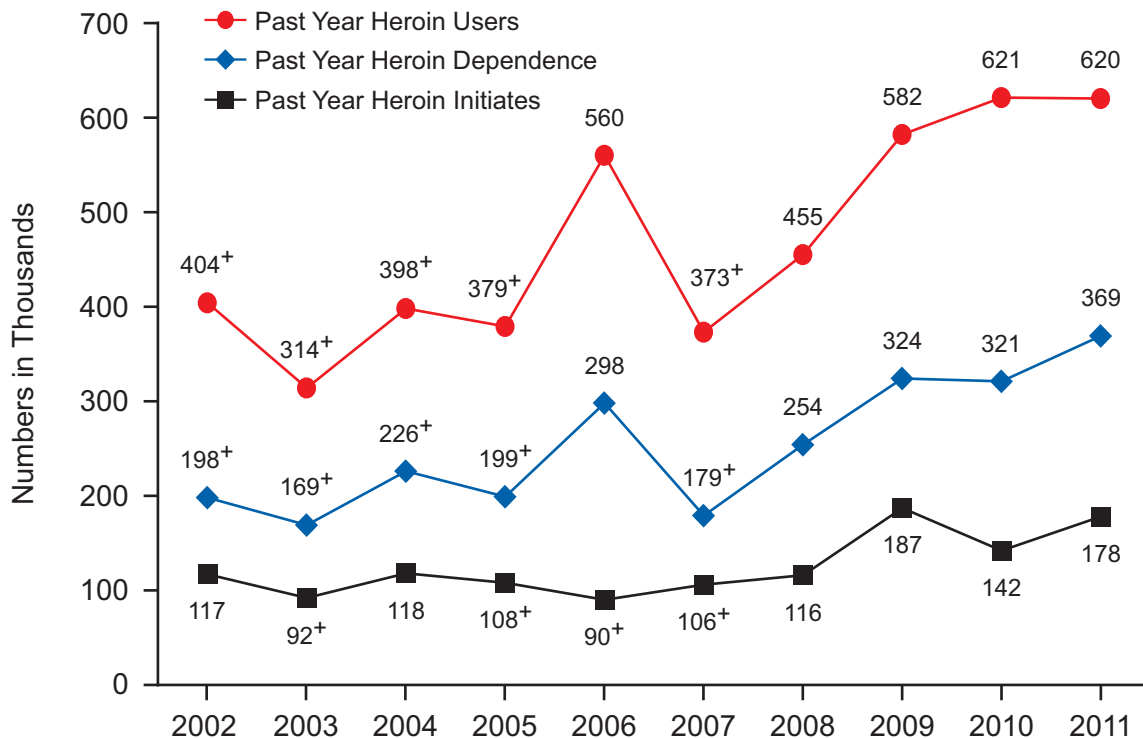

Heroin Use

Chapters 2 and 5 of this report note that the 2011 NSDUH data showed higher numbers of heroin users and initiates than in some prior years. These findings seem to support anecdotal reports that have suggested increasing use of heroin among young people. For example, news media reports have linked the increase in heroin use to nonmedical use of prescription pain relievers among young people, suggesting that some prescription pain reliever abusers have shifted to heroin. It is not possible in this summary report of the 2011 NSDUH findings to fully explore the potential association between pain reliever misuse and heroin use. In addition, a limitation of NSDUH and other household surveys is the difficulty in estimating heroin use prevalence because of the low prevalence of use in the general population, the likelihood of underreporting of use, and undercoverage of heroin users in a household sample. Nevertheless, despite the underestimation that is believed to be present, NSDUH's consistent methodology over time permits assessment of trends, providing an important baseline and descriptive background for studying the recent heroin problem. To provide stable estimates for assessing trends, a comparison of combined 2002-2005 estimates with 2009-2011 estimates is made.

Figure 8.6 shows the estimated annual numbers of past year heroin users, persons with past year heroin dependence, and first-time users (past year initiates) from 2002 to 2011. Numbers of past year heroin users and persons with heroin dependence increased from 2002 to 2011, and the number of past year initiates increased from 2003 to 2011. Estimates of the number of users for 2009, 2010, and 2011 yielded an annual average of 607,000 per year, compared with an annual average of 374,000 during 2002-2005. Similarly, the estimated number of new users increased from 109,000 per year during 2002-2005 to 169,000 per year during 2009-2011. The increase in initiation is evident among young adults aged 18 to 25 and adults aged 26 and older. There were 28,000 youth initiates per year in 2002-2005 and 27,000 in 2009-2011. Young adult initiates increased from 53,000 per year to 89,000 per year, and older adult initiates increased from 28,000 to 54,000 for these combined time periods. Past year use estimates for 2002-2005 and 2009-2011 showed the same pattern: for youths, estimates were

43,000 and 39,000; for young adults, the estimates were 124,000 and 208,000; and for older adults, the estimates were 207,000 and 361,000. MTF data indicated an increase for young adults aged 19 to 28 and a decrease for 10th graders in rates of past year heroin use between 2002 and 2011. MTF data did not indicate any changes among 8th and 12th graders between these 2 years.

Figure 8.6 Past Year Heroin Use, Heroin Dependence, and Heroin Initiates among Persons Aged 12 or Older: 2002-2011

⁺ Difference between this estimate and the 2011 estimate is statistically significant at the .05 level.

NSDUH has consistently found that about half or more of past year heroin users are dependent on heroin. Thus, it is not surprising that the number of persons with heroin dependence has risen along with the number of users. The average annual number of persons with heroin dependence increased from 198,000 per year during 2002-2005 to 338,000 during 2009-2011. The majority of these heroin-dependent persons were aged 26 or older. However, the annual average number of heroin-dependent young adults rose from 53,000 in 2002-2005 to 109,000 in 2009-2011. The annual average number of older adults who were dependent on heroin increased from 137,000 to 216,000 between these two periods. Youth heroin dependence estimates were 8,000 and 13,000, respectively.

Finally, the NSDUH estimated annual average number of persons receiving treatment in the past year for a heroin problem at a specialty substance abuse facility increased from 181,000 during 2002-2005 to 289,000 during 2009-2011. However, this increase in treatment for heroin is not evident in TEDS data from publicly funded treatment programs. Special analyses of TEDS admissions data indicated that there were 340,000 admissions for a heroin problem in 2002 and

314,000 in 2010. This decline could be associated with an increase in private-for-profit opioid treatment facilities during the past few years. Most of these private facilities are not included in TEDS data. There was also no increase in heroin-related emergency department visits according to DAWN results. DAWN estimated that there were 214,000 visits in 2004 and 225,000 in 2010 (CBHSQ, 2012). These apparently inconsistent findings based on data from service providers need further study.

-- Not available.

NOTE: NSDUH data are for persons aged 18 to 25. Some 2006 to 2010 NSDUH estimates may differ from previously published estimates due to updates (see Section B.3 in Appendix B of this report).

NOTE: MTF data were calculated for persons aged 19 to 24 using simple averages of modal age groups 19-20, 21-22, and 23-24 (source data at <http://www.monitoringthefuture.org/pubs.html>). Estimates may differ from those published previously due to rounding. For the 19 to 24 age group in the MTF data, significance tests were performed assuming independent samples between years an odd number of years apart because two distinct cohorts a year apart were monitored longitudinally at 2-year intervals. Although appropriate for comparisons of 2002, 2004, 2006, 2008, and 2010 estimates with 2011 estimates, this assumption results in conservative tests for comparisons of 2003, 2005, 2007, and 2009 data with 2011 estimates because it does not take into account covariances that are associated with repeated observations from the longitudinal samples. Estimates of covariances were not available.

^a Difference between this estimate and 2011 estimate is statistically significant at the .05 level.

¹ MTF data are for "narcotics other than heroin."

Appendix A: Description of the Survey

A.1 Sample Design

The sample design for the 2011 National Survey on Drug Use and Health (NSDUH)³ was an extension of a coordinated 5-year design providing estimates for all 50 States plus the District of Columbia initially for the years 2005 through 2009, then continuing through 2011. The respondent universe for NSDUH is the civilian, noninstitutionalized population aged 12 years old or older residing within the United States. The survey covers residents of households (persons living in houses/townhouses, apartments, condominiums; civilians living in housing on military bases, etc.) and persons in noninstitutional group quarters (e.g., shelters, rooming/boarded houses, college dormitories, migratory workers' camps, halfway houses). Excluded from the survey are persons with no fixed household address (e.g., homeless and/or transient persons not in shelters), active-duty military personnel, and residents of institutional group quarters, such as correctional facilities, nursing homes, mental institutions, and long-term hospitals.

The coordinated design for 2005 through 2009 facilitated a 50 percent overlap in second-stage units (area segments) within each successive 2-year period from 2005 through 2009. The 2010 and 2011 NSDUHs continued the 50 percent overlap by retaining half of the second-stage units from the previous survey. Those segments not retained are considered "retired" from use. Because the coordinated design enabled estimates to be developed by State in all 50 States plus the District of Columbia, States may be viewed as the first level of stratification and as a reporting variable.

In 2011, an oversample was included to help in measuring and reporting on the impact that the April 2010 Deepwater Horizon oil spill had on substance use and mental health along the gulf coast. To that end, the target sample was expanded by 2,000 cases in four Gulf Coast States (Alabama, Florida, Louisiana, and Mississippi), resulting in a total targeted national sample size of 69,500. The 2011 Gulf Coast Oversample (GCO) was attained by supplementing the NSDUH sample with 89 segments in GCO-designated counties and parishes in these four States. These 89 segments were retired from use in the 2009 and 2010 surveys. For more details on the GCO and information about the general 2011 NSDUH sample design, see the 2011 NSDUH sample design report by Morton, Martin, Shook-Sa, Chromy, and Hirsch (2012).

For the 50-State design, 8 States were designated as large sample States (California, Florida, Illinois, Michigan, New York, Ohio, Pennsylvania, and Texas) with pre-oversample target sample sizes of 3,600. In 2011, the actual sample sizes in these States ranged from 3,074 to 4,029.⁴ For the remaining 42 States and the District of Columbia, the pre-oversample target

³ Prior to 2002, the survey was known as the National Household Survey on Drug Abuse (NHSDA).

⁴ One large sample State, Pennsylvania, had a lower final sample size (3,074) because of interviews that were dropped due to data quality issues. Florida received a portion of the GCO supplement and therefore had a higher sample size (4,029).

sample size was 900. Sample sizes in these States ranged from 865 to 1,746 in 2011.⁵ This approach ensured there was sufficient sample in every State to support State estimation by either direct methods or small area estimation (SAE)⁶ while at the same time maintaining efficiency for national estimates.

States were first stratified into a total of 900 State sampling regions (SSRs) (48 regions in each large sample State and 12 regions in each small sample State). These regions were contiguous geographic areas designed to yield approximately the same number of interviews.⁷ Unlike the 1999 through 2001 NHSDAs and the 2002 through 2004 NSDUHs in which the first-stage sampling units were clusters of census blocks called area segments, the first stage of selection for the 2005 through 2011 NSDUHs was census tracts.⁸ This stage was included to contain sample segments within a single census tract to the extent possible.⁹

Within each SSR, 48 census tracts were selected with probability proportional to population size. Within sampled census tracts, adjacent census blocks were combined to form the second-stage sampling units or area segments. One area segment was selected within each sampled census tract with probability proportional to population size. Although only 24 segments were needed to support the coordinated 5-year sample, an additional 24 segments were selected to support any supplemental studies that the Substance Abuse and Mental Health Services Administration (SAMHSA) may choose to field. These 24 segments constituted the reserve sample and were available for use in 2010 and 2011. Eight reserve sample segments per SSR were fielded during the 2011 survey year. Four of these segments were retained from the 2010 survey, and four were selected for use in the 2011 survey.

These sampled segments were allocated equally into four separate samples, one for each 3-month period (calendar quarter) during the year. That is, a sample of addresses was selected from two segments¹⁰ in each calendar quarter so that the survey was relatively continuous in the field. In each of the area segments, a listing of all addresses was made from which a national sample of 216,521 addresses was selected. Of the selected addresses, 179,293 were determined to be eligible sample units. In these sample units (which can be either households or units within group quarters), sample persons were randomly selected using an automated screening procedure programmed in a handheld computer carried by the interviewers. The number of sample units completing the screening was 156,048. Youths aged 12 to 17 years and young adults aged 18 to

⁵ The State at the top end of the range (Louisiana, with a sample size of 1,746) included a portion of the GCO supplement.

⁶ SAE is a hierarchical Bayes modeling technique used to make State-level estimates for 25 measures related to substance use and mental health. For more details, see the *State Estimates of Substance Use and Mental Disorders from the 2009-2010 National Surveys on Drug Use and Health* (Hughes, Muhuri, Sathe, & Spagnola, 2012).

⁷ Sampling areas were defined using 2000 census geography. Counts of dwelling units (DUs) and population totals were obtained from the 2000 decennial census data supplemented with revised population counts from Nielsen Claritas.

⁸ Census tracts are relatively permanent statistical subdivisions of counties and parishes and provide a stable set of geographic units across decennial census periods.

⁹ Some census tracts had to be aggregated in order to meet the minimum DU requirement of 150 DUs in urban areas and 100 DUs in rural areas.

¹⁰ The sample was selected from up to four segments per calendar quarter in SSRs receiving the GCO supplement.

25 years were oversampled at this stage, with 12 to 17 year olds sampled at an actual rate of 87.2 percent and 18 to 25 year olds at a rate of 69.5 percent on average, when they were present in the sampled households or group quarters. Similarly, persons in age groups 26 or older were sampled at rates of 38.2 percent or less, with persons in the eldest age group (50 years or older) sampled at a rate of 8.9 percent on average. The overall population sampling rates were 0.09 percent for 12 to 17 year olds, 0.07 percent for 18 to 25 year olds, 0.02 percent for 26 to 34 year olds, 0.01 percent for 35 to 49 year olds, and 0.01 percent for those 50 or older. Nationwide, 88,536 persons were selected. Consistent with previous surveys in this series, the final respondent sample of 70,109 persons was representative of the U.S. general population (since 1991, the civilian, noninstitutionalized population) aged 12 or older. In addition, State samples were representative of their respective State populations. More detailed information on the disposition of the national screening and interview sample can be found in Appendix B.

A.2 Data Collection Methodology

The data collection method used in NSDUH involves in-person interviews with sample persons, incorporating procedures to increase respondents' cooperation and willingness to report honestly about their illicit drug use behavior. Confidentiality is stressed in all written and oral communications with potential respondents. Respondents' names are not collected with the data, and computer-assisted interviewing (CAI) methods are used to provide a private and confidential setting to complete the interview.

Introductory letters are sent to sampled addresses, followed by an interviewer visit. When contacting a dwelling unit (DU), the field interviewer (FI) asks to speak with an adult resident (aged 18 or older) of the household who can serve as the screening respondent. Using a handheld computer, the FI completes a 5-minute procedure with the screening respondent that involves listing all household members along with their basic demographic data. The computer uses the demographic data in a preprogrammed selection algorithm to select zero to two sample persons, depending on the composition of the household. This selection process is designed to provide the necessary sample sizes for the specified population age groupings. In areas where a third or more of the households contain Spanish-speaking residents, the initial introductory letters written in English are mailed with a Spanish version on the back. All interviewers carry copies of this letter in Spanish. If the interviewer is not certified bilingual, he or she will use preprinted Spanish cards to attempt to find someone in the household who speaks English and who can serve as the screening respondent or who can translate for the screening respondent. If no one is available, the interviewer will schedule a time when a Spanish-speaking interviewer can come to the address. In households where a language other than Spanish is encountered, another language card is used to attempt to find someone who speaks English to complete the screening.

The NSDUH interview can be completed in English or Spanish, and both versions have the same content. If the sample person prefers to complete the interview in Spanish, a certified bilingual interviewer is sent to the address to conduct the interview. Because the interview is not translated into any other language, if a sample person does not speak English or Spanish, the interview is not conducted.

Immediately after the completion of the screener, interviewers attempt to conduct the NSDUH interview with each sample person in the household. The interviewer requests the

selected respondent to identify a private area in the home to conduct the interview away from other household members. The interview averages about an hour and includes a combination of CAPI (computer-assisted personal interviewing, in which the interviewer reads the questions) and ACASI (audio computer-assisted self-interviewing).

The NSDUH interview consists of core and noncore (i.e., supplemental) sections. A core set of questions critical for basic trend measurement of prevalence estimates remains in the survey every year and comprises the first part of the interview. Noncore questions, or modules, that can be revised, dropped, or added from year to year make up the remainder of the interview. The core consists of initial demographic items (which are interviewer-administered) and self-administered questions pertaining to the use of tobacco, alcohol, marijuana, cocaine, crack cocaine, heroin, hallucinogens, inhalants, pain relievers, tranquilizers, stimulants, and sedatives. Topics in the remaining noncore self-administered sections include (but are not limited to) injection drug use, perceived risks of substance use, substance dependence or abuse, arrests, treatment for substance use problems, pregnancy and health care issues, and mental health issues. Noncore demographic questions (which are interviewer-administered and follow the ACASI questions) address such topics as immigration, current school enrollment, employment and workplace issues, health insurance coverage, and income. In practice, some of the noncore portions of the interview have remained in the survey, relatively unchanged, from year to year (e.g., current health insurance coverage, employment).

Thus, the interview begins in CAPI mode with the FI reading the questions from the computer screen and entering the respondent's replies into the computer. The interview then transitions to the ACASI mode for the sensitive questions. In this mode, the respondent can read the questions silently on the computer screen and/or listen to the questions read through headphones and enter his or her responses directly into the computer. At the conclusion of the ACASI section, the interview returns to the CAPI mode with the FI completing the questionnaire. Each respondent who completes a full interview is given a \$30 cash payment as a token of appreciation for his or her time.

No personal identifying information about the respondent is captured in the CAI record. FIs transmit the completed interview data to RTI in Research Triangle Park, North Carolina, via home telephone analog lines.

After the data are transmitted to RTI, certain cases are selected for verification. The respondents are contacted by RTI to verify the quality of an FI's work based on information that respondents provide at the end of screening (if no one is selected for an interview at the DU or the entire DU is ineligible for the study) or at the end of the interview. For the screening interview, the adult DU member who served as the screening respondent provides his or her first name and telephone number to the FI, who enters the information into a handheld computer and transmits the data to RTI. For completed interviews, respondents write their home telephone number and mailing address on a quality control form and seal the form in a preaddressed envelope that FIs mail back to RTI. All contact information is kept completely separate from the answers provided during the screening or interview.

Samples of respondents who completed screenings or interviews are randomly selected for verification. These cases are called by telephone interviewers who ask scripted questions

designed to determine the accuracy and quality of the data collected. Any cases discovered to have a problem or discrepancy are flagged and routed to a small specialized team of telephone interviewers who recontact respondents for further investigation of the issue(s). Depending on the amount of an FI's work that cannot be verified through telephone verification, including bad telephone numbers (e.g., incorrect number, disconnected, not in service), a field verification may be conducted. Field verifications involve another FI returning to the sampled DU to verify the accuracy and quality of the data in person. If the verification procedures identify situations in which an FI has falsified data, the FI no longer works on NSDUH. All cases completed that quarter by the FI who falsified data are reworked by the FI conducting the field verification.

A.3 Data Processing

Data that FIs transmit to RTI are processed to create a raw data file in which no logical editing of the data has been done. The raw data file consists of one record for each transmitted interview. Cases are eligible to be treated as final respondents only if they provided data on lifetime use of cigarettes and at least 9 out of 13 of the other substances in the core section of the questionnaire. Written responses to questions (e.g., names of other drugs that were used) are assigned numeric codes as part of the data processing procedures. Even though editing and consistency checks are done by the CAI program during the interview, additional, more complex edits and consistency checks are completed at RTI. Additionally, statistical imputation is used to replace missing or ambiguous values after editing for some key variables. Analysis weights are created so that estimates will be representative of the target population. Details of the editing, imputation, and weighting procedures for 2011 will appear in the *2011 NSDUH Methodological Resource Book*, which is in process. Until that volume becomes available, refer to the *2010 NSDUH Methodological Resource Book* (RTI International, 2012).

A.3.1 Data Coding and Logical Editing

With the exception of industry and occupation data, coding of written answers that respondents or interviewers typed was performed at RTI for the 2011 NSDUH. These written answers include mentions of drugs that respondents had used or other responses that did not fit a previous response option (subsequently referred to as "OTHER, Specify" data). Coding of the "OTHER, Specify" variables was accomplished through computer-assisted survey procedures and the use of a secure Web site that allowed for coding and review of the data. The computer-assisted procedures entailed a database check for a given "OTHER, Specify" variable that contained typed entries and the associated numeric codes. If an exact match was found between the typed response and an entry in the system, the computer-assisted procedures assigned the appropriate numeric code. Typed responses that did not match an existing entry were coded through the Web-based coding system. Data on the industries in which respondents worked and respondents' occupations were assigned numeric industry and occupation codes by staff at the U.S. Census Bureau.

As noted above, the CAI program included checks that alerted respondents or interviewers when an entered answer was inconsistent with a previous answer in a given module. In this way, the inconsistency could be resolved while the interview was in progress. However, not every inconsistency was resolved during the interview, and the CAI program did not include checks for every possible inconsistency that might have occurred in the data.

Therefore, the first step in processing the raw NSDUH data was logical editing of the data. Logical editing involved using data from within a respondent's record to (a) reduce the amount of item nonresponse (i.e., missing data) in interview records, including identification of items that were legitimately skipped; (b) make related data elements consistent with each other; and (c) identify ambiguities or inconsistencies to be resolved through statistical imputation procedures (see Section A.3.2).

For example, if respondents reported that they never used a given drug, the CAI logic skipped them out of all remaining questions about use of that drug. In the editing procedures, the skipped variables were assigned codes to indicate that the respondents were lifetime nonusers. Similarly, respondents were instructed in the prescription psychotherapeutics modules (i.e., pain relievers, tranquilizers, stimulants, and sedatives) not to report the use of over-the-counter (OTC) drugs. Therefore, if a respondent's only report of lifetime use of a particular type of "prescription" psychotherapeutic drug was for an OTC drug, the respondent was logically inferred never to have been a nonmedical user of the prescription drugs in that psychotherapeutic category.

In addition, respondents could report that they were lifetime users of a drug but not provide specific information on when they last used it. In this situation, a temporary "indefinite" value for the most recent period of use was assigned to the edited recency-of-use variable (e.g., "Used at some point in the lifetime LOGICALLY ASSIGNED"), and a final, specific value was statistically imputed. The editing procedures for key drug use variables also involved identifying inconsistencies between related variables so that these inconsistencies could be resolved through statistical imputation. For example, if a respondent reported last using a drug more than 12 months ago and also reported first using it at his or her current age, both of those responses could not be true. In this example, the inconsistent period of most recent use was replaced with an "indefinite" value, and the inconsistent age at first use was replaced with a missing data code. These indefinite or missing values were subsequently imputed through statistical procedures to yield consistent data for the related measures, as discussed in the next section.

A.3.2 Statistical Imputation

For some key variables that still had missing or ambiguous values after editing, statistical imputation was used to replace these values with appropriate response codes. For example, a response is ambiguous if the editing procedures assigned a respondent's most recent use of a drug to "Used at some point in the lifetime," with no definite period within the lifetime. In this case, the imputation procedure assigns a value for when the respondent last used the drug (e.g., in the past 30 days, more than 30 days ago but within the past 12 months, more than 12 months ago). Similarly, if a response is completely missing, the imputation procedures replace missing values with nonmissing ones.

For most variables, missing or ambiguous values are imputed in NSDUH using a methodology called predictive mean neighborhoods (PMN), which was developed specifically for the 1999 survey and has been used in all subsequent survey years. PMN allows for the following: (1) the ability to use covariates to determine donors is greater than that offered in the hot-deck imputation procedure, (2) the relative importance of covariates can be determined by standard modeling techniques, (3) the correlations across response variables can be accounted for

by making the imputation multivariate, and (4) sampling weights can be easily incorporated in the models. The PMN method has some similarity with the predictive mean matching method of Rubin (1986) except that, for the donor records, Rubin used the observed variable value (not the predictive mean) to compute the distance function. Also, the well-known method of nearest neighbor imputation is similar to PMN, except that the distance function is in terms of the original predictor variables and often requires somewhat arbitrary scaling of discrete variables. PMN is a combination of a model-assisted imputation methodology and a random nearest neighbor hot-deck procedure. The hot-deck procedure within the PMN method ensures that missing values are imputed to be consistent with nonmissing values for other variables. Whenever feasible, the imputation of variables using PMN is multivariate, in which imputation is accomplished on several response variables at once. Variables imputed using PMN are the core demographic variables, core drug use variables (recency of use, frequency of use, and age at first use), income, health insurance, and noncore demographic variables for work status, immigrant status, and the household roster.

In the modeling stage of PMN, the model chosen depends on the nature of the response variable. In the 2011 NSDUH, the models included binomial logistic regression, multinomial logistic regression, Poisson regression, and ordinary linear regression, where the models incorporated the sampling design weights.

In general, hot-deck imputation replaces an item nonresponse (missing or ambiguous value) with a recorded response that is donated from a "similar" respondent who has nonmissing data. For random nearest neighbor hot-deck imputation, the missing or ambiguous value is replaced by a responding value from a donor randomly selected from a set of potential donors. Potential donors are those defined to be "close" to the unit with the missing or ambiguous value according to a predefined function called a distance metric. In the hot-deck procedure of PMN, the set of candidate donors (the "neighborhood") consists of respondents with complete data who have a predicted mean close to that of the item nonrespondent. The predicted means are computed both for respondents with and without missing data, which differs from Rubin's method where predicted means are not computed for the donor respondent (Rubin, 1986). In particular, the neighborhood consists of either the set of the closest 30 respondents or the set of respondents with a predicted mean (or means) within 5 percent of the predicted mean(s) of the item nonrespondent, whichever set is smaller. If no respondents are available who have a predicted mean (or means) within 5 percent of the item nonrespondent, the respondent with the predicted mean(s) closest to that of the item nonrespondent is selected as the donor.

In the univariate case (where only one variable is imputed using PMN), the neighborhood of potential donors is determined by calculating the relative distance between the predicted mean for an item nonrespondent and the predicted mean for each potential donor, then choosing those means defined by the distance metric. The pool of donors is restricted further to satisfy logical constraints whenever necessary (e.g., age at first crack use must not be less than age at first cocaine use).

Whenever possible, missing or ambiguous values for more than one response variable are considered together. In this (multivariate) case, the distance metric is a Mahalanobis distance, which takes into account the correlation between variables (Manly, 1986), rather than a Euclidean distance. The Euclidean distance is the square root of the sum of squared differences

between each element of the predictive mean vector for the respondent and the predictive mean vector for the nonrespondent. The Mahalanobis distance standardizes the Euclidean distance by the variance-covariance matrix, which is appropriate for random variables that are correlated or have heterogeneous variances. Whether the imputation is univariate or multivariate, only missing or ambiguous values are replaced, and donors are restricted to be logically consistent with the response variables that are not missing. Furthermore, donors are restricted to satisfy "likeness constraints" whenever possible. That is, donors are required to have the same values for variables highly correlated with the response. For example, donors for the age at first use variable are required to be of the same age as recipients, if at all possible. If no donors are available who meet these conditions, these likeness constraints can be loosened. Further details on the PMN methodology are provided by Singh, Grau, and Folsom (2002).

Although statistical imputation could not proceed separately within each State due to insufficient pools of donors, information about each respondent's State of residence was incorporated in the modeling and hot-deck steps. For most drugs, respondents were separated into three "State usage" categories as follows: respondents from States with high usage of a given drug were placed in one category, respondents from States with medium usage into another, and the remainder into a third category. This categorical "State rank" variable was used as one set of covariates in the imputation models. In addition, eligible donors for each item nonrespondent were restricted to be of the same State usage category (i.e., the same "State rank") as the nonrespondent.

In the 2011 NSDUH, the majority of variables that underwent statistical imputation required less than 5 percent of their records to be logically assigned or statistically imputed. Variables for measures that are highly sensitive or that may not be known to younger respondents (e.g., family income) often have higher rates of item nonresponse. In addition, certain variables that are subject to a greater number of skip patterns and consistency checks (e.g., frequency of use in the past 12 months and past 30 days) often require greater amounts of imputation.

A.3.3 Development of Analysis Weights

The general approach to developing and calibrating analysis weights involved developing design-based weights as the product of the inverse of the selection probabilities at each selection stage. Since 2005, NSDUH has used a four-stage sample selection scheme in which an extra selection stage of census tracts was added before the selection of a segment. Thus, the design-based weights, d_k , incorporate an extra layer of sampling selection to reflect the sample design change. Adjustment factors, $a_k(\lambda)$, then were applied to the design-based weights to adjust for nonresponse, to poststratify to known population control totals, and to control for extreme weights when necessary. In view of the importance of State-level estimates with the 50-State design, it was necessary to control for a much larger number of known population totals. Several other modifications to the general weight adjustment strategy that had been used in past surveys also were implemented for the first time beginning with the 1999 CAI sample.

Weight adjustments were based on a generalization of Deville and Särndal's (1992) logit model. This generalized exponential model (GEM) (Folsom & Singh, 2000) incorporates unit-specific bounds $(\ell_k, u_k), k \in s$, for the adjustment factor $a_k(\lambda)$ as follows:

$$a_k(\lambda) = \frac{\ell_k(u_k - c_k) + u_k(c_k - \ell_k)\exp(A_k x_k' \lambda)}{(u_k - c_k) + (c_k - \ell_k)\exp(A_k x_k' \lambda)},$$

where c_k are prespecified centering constants, such that $\ell_k < c_k < u_k$ and $A_k = (u_k - \ell_k) / (u_k - c_k)(c_k - \ell_k)$. The variables ℓ_k, c_k , and u_k are user-specified bounds, and λ is the column vector of p model parameters corresponding to the p covariates x . The λ -parameters are estimated by solving

$$\sum_s x_k d_k a_k(\lambda) - \tilde{T}_x = 0,$$

where \tilde{T}_x denotes control totals that could be either nonrandom, as is generally the case with poststratification, or random, as is generally the case for nonresponse adjustment.

The final weights $w_k = d_k a_k(\lambda)$ minimize the distance function $\Delta(w, d)$ defined as

$$\Delta(w, d) = \sum_{k \in s} \frac{d_k}{A_k} \left\{ (a_k - \ell_k) \log \frac{a_k - \ell_k}{c_k - \ell_k} + (u_k - a_k) \log \frac{u_k - a_k}{u_k - c_k} \right\}.$$

This general approach was used at several stages of the weight adjustment process, including (1) adjustment of household weights for nonresponse at the screener level, (2) poststratification of household weights to meet population controls for various household-level demographics by State, (3) adjustment of household weights for extremes, (4) poststratification of selected person weights, (5) adjustment of responding person weights for nonresponse at the questionnaire level, (6) poststratification of responding person weights, and (7) adjustment of responding person weights for extremes.

Every effort was made to include as many relevant State-specific covariates (typically defined by demographic domains within States) as possible in the multivariate models used to calibrate the weights (nonresponse adjustment and poststratification steps). Because further subdivision of State samples by demographic covariates often produced small cell sample sizes, it was not possible to retain all State-specific covariates (even after meaningful collapsing of covariate categories) and still estimate the necessary model parameters with reasonable precision. Therefore, a hierarchical structure was used in grouping States with covariates defined at the national level, at the census division level within the Nation, at the State group within the census division, and, whenever possible, at the State level. In every case, the controls for the total population within a State and the five age groups (12 to 17, 18 to 25, 26 to 34, 35 to 49, 50 or older) within a State were maintained except that, in the last step of poststratification of person weights, six age groups (12 to 17, 18 to 25, 26 to 34, 35 to 49, 50 to 64, 65 or older) were used. Census control totals by age, race, gender, and Hispanic origin were required for the

civilian, noninstitutionalized population of each State. Beginning with the 2002 NSDUH, the Population Estimates Branch of the U.S. Census Bureau has produced the necessary population estimates for the same year as each NSDUH survey in response to a special request.

Census control totals for the 2011 NSDUH weights were based on population estimates from the 2010 decennial census, whereas the control totals for the 2010 NSDUH weights still were based on the 2000 census. Section B.4.3 in Appendix B discusses the results of an investigation assessing the effects of using control totals based on the 2010 census instead of the 2000 census for estimating substance use in 2010.

Consistent with the surveys from 1999 onward, control of extreme weights through separate bounds for adjustment factors was incorporated into the GEM calibration processes for both nonresponse and poststratification. This is unlike the traditional method of winsorization in which extreme weights are truncated at prespecified levels and the trimmed portions of weights are distributed to the nontruncated cases. In GEM, it is possible to set bounds around the prespecified levels for extreme weights, then the calibration process provides an objective way of deciding the extent of adjustment (or truncation) within the specified bounds. A step was included to poststratify the household-level weights to obtain census-consistent estimates based on the household rosters from all screened households. An additional step poststratified the selected person sample to conform to the adjusted roster estimates. This additional step takes advantage of the inherent two-phase nature of the NSDUH design. The respondent poststratification step poststratified the respondent person sample to external census data (defined within the State whenever possible, as discussed above).

For certain populations of interest, 2 years of NSDUH data were combined to obtain annual averages. The person-level weights for estimates based on the annual averages were obtained by dividing the analysis weights for the 2 specific years by a factor of 2.

In the 2011 NSDUH, the GCO sample was integrated into the main study sample. The weighting process accounted for the oversampling without additional adjustment needing to be implemented. Special analysis weights were developed for studies focused on the gulf coast area, but these were not used for any estimates for this report.

Appendix B: Statistical Methods and Measurement

B.1 Target Population

The estimates of drug use prevalence from the National Survey on Drug Use and Health (NSDUH) are designed to describe the target population of the survey—the civilian, noninstitutionalized population aged 12 or older living in the United States. This population includes almost 98 percent of the total U.S. population aged 12 or older. However, it excludes some small subpopulations that may have very different drug use patterns. For example, the survey excludes active military personnel, who have been shown to have significantly lower rates of illicit drug use. The survey also excludes two groups that have been shown to have higher rates of illicit drug use: persons living in institutional group quarters, such as prisons and residential drug use treatment centers, and homeless persons not living in a shelter. Readers are reminded to consider the exclusion of these subpopulations when interpreting results. Appendix C describes other surveys that provide data for some of these populations.

B.2 Sampling Error and Statistical Significance

This report includes national estimates that were drawn from a set of tables referred to as "detailed tables" that are available at <http://www.samhsa.gov/data/>. The national estimates, along with the associated standard errors (SEs, which are the square roots of the variances), were computed for all detailed tables using a multiprocedure package, SUDAAN[®] Software for Statistical Analysis of Correlated Data. This software accounts for the complex survey design of NSDUH in estimating the SEs (RTI International, 2008). The final, nonresponse-adjusted, and poststratified analysis weights were used in SUDAAN to compute unbiased design-based drug use estimates.

The sampling error of an estimate is the error caused by the selection of a sample instead of conducting a census of the population. The sampling error may be reduced by selecting a large sample and/or by using efficient sample design and estimation strategies, such as stratification, optimal allocation, and ratio estimation. The use of probability sampling methods in NSDUH allows estimation of sampling error from the survey data. SEs have been calculated using SUDAAN for all estimates presented in this report using a Taylor series linearization approach that takes into account the effects of NSDUH's complex design features. The SEs are used to identify unreliable estimates and to test for the statistical significance of differences between estimates.

B.2.1 Variance Estimation for Totals

The variances and SEs of estimates of means and proportions can be calculated reasonably well in SUDAAN using a Taylor series linearization approach. Estimates of means or proportions, \hat{p}_d , such as drug use prevalence estimates for a domain d , can be expressed as a ratio estimate:

$$\hat{p}_d = \frac{\hat{Y}_d}{\hat{N}_d},$$

where \hat{Y}_d is a linear statistic estimating the number of substance users in the domain d and \hat{N}_d is a linear statistic estimating the total number of persons in domain d (including both users and nonusers). The SUDAAN software package is used to calculate direct estimates of \hat{Y}_d and \hat{N}_d (and, therefore, \hat{p}_d) and also can be used to estimate their respective SEs. A Taylor series approximation method implemented in SUDAAN provides the estimate for the SE of \hat{p}_d .

When the domain size, \hat{N}_d , is free of sampling error, an estimate of the SE for the total number of substance users is

$$SE(\hat{Y}_d) = \hat{N}_d SE(\hat{p}_d).$$

This approach is theoretically correct when the domain size estimates, \hat{N}_d , are among those forced to match their respective U.S. Census Bureau population estimates through the weight calibration process. In these cases, \hat{N}_d is not subject to a sampling error induced by the NSDUH design. Section A.3.3 in Appendix A contains further information about the weight calibration process. In addition, more detailed information about the weighting procedures for 2011 will appear in the *2011 NSDUH Methodological Resource Book*, which is in process. Until that volume becomes available, refer to the *2010 NSDUH Methodological Resource Book* (RTI International, 2012).

For estimated domain totals, \hat{Y}_d , where \hat{N}_d is not fixed (i.e., where domain size estimates are not forced to match the U.S. Census Bureau population estimates), this formulation still may provide a good approximation if it can be assumed that the sampling variation in \hat{N}_d is negligible relative to the sampling variation in \hat{p}_d . This is a reasonable assumption for many cases in this study.

For some subsets of domain estimates, the above approach can yield an underestimate of the SE of the total when \hat{N}_d was subject to considerable variation. Because of this underestimation, alternatives for estimating SEs of totals were implemented. Since the 2005 NSDUH report, a "mixed" method approach has been implemented for all detailed tables to improve the accuracy of SEs and to better reflect the effects of poststratification on the variance of total estimates. This approach assigns the methods of SE calculation to domains (i.e., subgroups for which the estimates were calculated) within tables so that all estimates among a select set of domains with fixed \hat{N}_d were calculated using the formula above, and all other estimates were calculated directly in SUDAAN, regardless of what the other estimates are within the same table. The set of domains considered controlled (i.e., those with a fixed \hat{N}_d) was

restricted to main effects and two-way interactions in order to maintain continuity between years. Domains consisting of three-way interactions may be controlled in a single year but not necessarily in preceding or subsequent years. The use of such SEs did not affect the SE estimates for the corresponding proportions presented in the same sets of tables because all SEs for means and proportions are calculated directly in SUDAAN. As a result of the use of this mixed-method approach, the SEs for the total estimates within many detailed tables were calculated differently from those in NSDUH reports prior to the 2005 report.

Table B.1 at the end of this appendix contains a list of domains with a fixed \hat{N}_d that were used in the weight calibration process. This table includes both the main effects and two-way interactions and may be used to identify the method of SE calculation employed for estimates of totals. For example, Table 1.23 in the 2011 detailed tables presents estimates of illicit drug use among persons aged 18 or older within the domains of gender, Hispanic origin and race, education, and current employment. Estimates among the total population (age main effect), males and females (age by gender interaction), and Hispanics and non-Hispanics (age by Hispanic origin interaction) were treated as controlled in this table, and the formula above was used to calculate the SEs. The SEs for all other estimates, including white and black or African American (age by Hispanic origin by race interaction) were calculated directly from SUDAAN. Estimates presented in this report for racial groups are for non-Hispanics. Thus, the domain for whites by age group in the weight calibration process in Table B.1 is a two-way interaction. However, published estimates for whites by age group in this report and in the 2011 detailed tables actually represent a three-way interaction: white by Hispanic origin (i.e., not Hispanic) by age group.

B.2.2 Suppression Criteria for Unreliable Estimates

As has been done in past NSDUH reports, direct estimates from NSDUH that are designated as unreliable are not shown in this report and are noted by asterisks (*) in figures containing such estimates. The criteria used to define unreliability of direct estimates from NSDUH are based on the prevalence (for proportion estimates), relative standard error (RSE) (defined as the ratio of the SE over the estimate), nominal (actual) sample size, and effective sample size for each estimate. These suppression criteria for various NSDUH estimates are summarized in Table B.2 at the end of this appendix.

Proportion estimates (\hat{p}), or rates, within the range $[0 < \hat{p} < 1]$, and the corresponding estimated numbers of users were suppressed if

$$\text{RSE}[-\ln(\hat{p})] > .175 \text{ when } \hat{p} \leq .5$$

or

$$\text{RSE}[-\ln(1 - \hat{p})] > .175 \text{ when } \hat{p} > .5.$$

Using a first-order Taylor series approximation to estimate $\text{RSE}[-\ln(\hat{p})]$ and $\text{RSE}[-\ln(1 - \hat{p})]$, the following equation was derived and used for computational purposes when applying a suppression rule dependent on effective sample size:

$$\frac{SE(\hat{p}) / \hat{p}}{-\ln(\hat{p})} > .175 \text{ when } \hat{p} \leq .5$$

or

$$\frac{SE(\hat{p}) / (1 - \hat{p})}{-\ln(1 - \hat{p})} > .175 \text{ when } \hat{p} > .5 .$$

The separate formulas for $\hat{p} \leq .5$ and $\hat{p} > .5$ produce a symmetric suppression rule; that is, if \hat{p} is suppressed, $1 - \hat{p}$ will be suppressed as well (see Figure B.1 following Table B.2). When $.05 < \hat{p} < .95$, the symmetric properties of the rule produce a local minimum effective sample size of 50 at $\hat{p} = .2$ and at $\hat{p} = .8$. Using the minimum effective sample size for the suppression rule would mean that estimates of \hat{p} between .05 and .95 would be suppressed if their corresponding effective sample sizes were less than 50. Within this same interval, a local maximum effective sample size of 68 is found at $\hat{p} = .5$. To simplify requirements and maintain a conservative suppression rule, estimates of \hat{p} between .05 and .95 were suppressed if they had an effective sample size below 68.

In addition, a minimum nominal sample size suppression criterion ($n = 100$) that protects against unreliable estimates caused by small design effects and small nominal sample sizes was employed; Table B.2 shows a formula for calculating design effects. Prevalence estimates also were suppressed if they were close to 0 or 100 percent (i.e., if $\hat{p} < .00005$ or if $\hat{p} \geq .99995$).

Estimates of totals were suppressed if the corresponding prevalence rates were suppressed. Estimates of means that are not bounded between 0 and 1 (e.g., mean of age at first use) were suppressed if the RSEs of the estimates were larger than .5 or if the nominal sample size was smaller than 10 respondents.

B.2.3 Statistical Significance of Differences

This section describes the methods used to compare prevalence estimates in this report. Customarily, the observed difference between estimates is evaluated in terms of its statistical significance. Statistical significance is based on the p value of the test statistic and refers to the probability that a difference as large as that observed would occur because of random variability in the estimates if there were no difference in the prevalence estimates for the population groups being compared. The significance of observed differences in this report is reported at the .05 level. When comparing prevalence estimates, the null hypothesis (no difference between prevalence estimates) was tested against the alternative hypothesis (there is a difference in prevalence estimates) using the standard difference in proportions test expressed as

$$Z = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\text{var}(\hat{p}_1) + \text{var}(\hat{p}_2) - 2 \text{cov}(\hat{p}_1, \hat{p}_2)}},$$

where \hat{p}_1 = first prevalence estimate, \hat{p}_2 = second prevalence estimate, $\text{var}(\hat{p}_1)$ = variance of first prevalence estimate, $\text{var}(\hat{p}_2)$ = variance of second prevalence estimate, and $\text{cov}(\hat{p}_1, \hat{p}_2)$ = covariance between \hat{p}_1 and \hat{p}_2 . In cases where significance tests between years were performed, the prevalence estimate from the earlier year becomes the first estimate, and the prevalence estimate from the later year becomes the second estimate (e.g., 2010 is the first estimate and 2011 the second).

Under the null hypothesis, Z is asymptotically distributed as a standard normal random variable. Therefore, calculated values of Z can be referred to the unit normal distribution to determine the corresponding probability level (i.e., p value). Because the covariance term between the two estimates is not necessarily zero, SUDAAN was used to compute estimates of Z along with the associated p values using the analysis weights and accounting for the sample design as described in Appendix A. A similar procedure and formula for Z were used for estimated totals. Whenever it was necessary to calculate the SE outside of SUDAAN (i.e., when domains were forced by the weighting process to match their respective U.S. Census Bureau population estimates), the corresponding test statistics also were computed outside of SUDAAN.

When comparing population subgroups across three or more levels of a categorical variable, log-linear chi-square tests of independence of the subgroups and the prevalence variables were conducted using SUDAAN in order to first control the error level for multiple comparisons. If Shah's Wald F test (transformed from the standard Wald chi-square) indicated overall significant differences, the significance of each particular pairwise comparison of interest was tested using SUDAAN analytic procedures to properly account for the sample design (RTI International, 2008). Using the published estimates and SEs to perform independent t tests for the difference of proportions usually will provide the same results as tests performed in SUDAAN. However, where the significance level is borderline, results may differ for two reasons: (1) the covariance term is included in SUDAAN tests, whereas it is not included in independent t tests; and (2) the reduced number of significant digits shown in the published estimates may cause rounding errors in the independent t tests.

As part of a comparative analysis discussed in Chapter 8, prevalence estimates from the Monitoring the Future (MTF) study, sponsored by the National Institute on Drug Abuse (NIDA), were presented for recency measures of selected substances (see Tables 8.1 to 8.6). The analyses focused on prevalence estimates for 8th and 10th graders and prevalence estimates for young adults aged 19 to 24 for 2002 through 2011. Estimates for the 8th and 10th grade students were calculated using MTF data as the simple average of the 8th and 10th grade estimates. Estimates for young adults aged 19 to 24 were calculated using MTF data as the simple average of three modal age groups: 19 and 20 years, 21 and 22 years, and 23 and 24 years. Published results were not available from NIDA for significant differences in prevalence estimates between years for these subgroups, so testing was performed using information that was available.

For the 8th and 10th grade average estimates, tests of differences were performed between 2011 and the 9 prior years. Estimates for persons in grade 8 and grade 10 were considered independent, simplifying the calculation of variances for the combined grades. Across years, the estimates for 2011 involved samples independent of those in 2002 to 2009. For 2010 and 2011, however, the sample of schools overlapped 50 percent, creating a covariance in

the estimates. Design effects published in Johnston et al. (2012) for adjacent and nonadjacent year testing were used.

For the 19- to 24-year-old age group, tests of differences were done assuming independent samples between years an odd number of years apart because two distinct cohorts a year apart were monitored longitudinally at 2-year intervals. This is appropriate for comparisons of 2002, 2004, 2006, 2008, and 2010 data with 2011 data. However, this assumption results in conservative tests for comparisons of 2003, 2005, 2007, and 2009 data with 2011 data because testing did not take into account covariances associated with repeated observations from the longitudinal samples. Estimates of covariances were not available.

Complete details on testing between NSDUH and MTF can be found in Section B.2.3 in Appendix B of the 2010 national findings report (Center for Behavioral Health Statistics and Quality [CBHSQ], 2011). This discussion also includes variance estimation in the MTF data for testing between adjacent survey years.

B.3 Other Information on Data Accuracy

The accuracy of survey estimates can be affected by nonresponse, coding errors, computer processing errors, errors in the sampling frame, reporting errors, and other errors not due to sampling. These types of "nonsampling errors" and their impact are reduced through data editing, statistical adjustments for nonresponse, close monitoring and periodic retraining of interviewers, and improvement in quality control procedures.

Although these types of errors often can be much larger than sampling errors, measurement of most of these errors is difficult. However, some indication of the effects of some types of these errors can be obtained through proxy measures, such as response rates, and from other research studies.

B.3.1 Screening and Interview Response Rate Patterns

In 2011, respondents continued to receive a \$30 incentive in an effort to maximize response rates. The weighted screening response rate (SRR) is defined as the weighted number of successfully screened households¹¹ divided by the weighted number of eligible households (as defined in Table B.3), or

$$SRR = \frac{\sum w_{hh} complete_{hh}}{\sum w_{hh} eligible_{hh}},$$

where w_{hh} is the inverse of the unconditional probability of selection for the household and excludes all adjustments for nonresponse and poststratification defined in Section A.3.3 of Appendix A. Of the 179,293 eligible households sampled for the 2011 NSDUH, 156,048 were screened successfully, for a weighted screening response rate of 87.0 percent (Table B.3). At the

¹¹ A successfully screened household is one in which all screening questionnaire items were answered by an adult resident of the household and either zero, one, or two household members were selected for the NSDUH interview.

person level, the weighted interview response rate (IRR) is defined as the weighted number of respondents divided by the weighted number of selected persons (see Table B.4), or

$$IRR = \frac{\sum w_i \text{complete}_i}{\sum w_i \text{selected}_i},$$

where w_i is the inverse of the probability of selection for the person and includes household-level nonresponse and poststratification adjustments (adjustments 1, 2, and 3 in Section A.3.3 of Appendix A). To be considered a completed interview, a respondent must provide enough data to pass the usable case rule.¹² In the 156,048 screened households, a total of 88,536 sample persons were selected, and completed interviews were obtained from 70,109 of these sample persons, for a weighted IRR of 74.4 percent (Table B.4). A total of 13,311 (18.1 percent) sample persons were classified as refusals or parental refusals, 2,917 (3.4 percent) were not available or never at home, and 2,199 (4.1 percent) did not participate for various other reasons, such as physical or mental incompetence or language barrier (see Table B.4, which also shows the distribution of the selected sample by interview code and age group). Among demographic subgroups, the weighted IRR was higher among 12 to 17 year olds (85.0 percent), females (76.1 percent), blacks (79.8 percent), persons in the South (76.9 percent), and residents of nonmetropolitan areas (77.0 percent) than among other related groups (Table B.5).

The overall weighted response rate, defined as the product of the weighted screening response rate and weighted interview response rate or

$$ORR = SRR \times IRR$$

was 64.7 percent in 2011. Nonresponse bias can be expressed as the product of the nonresponse rate ($1 - R$) and the difference between the characteristic of interest between respondents and nonrespondents in the population ($P_r - P_{nr}$). By maximizing NSDUH response rates, it is hoped that the bias due to the difference between the estimates from respondents and nonrespondents is minimized. Drug use surveys are particularly vulnerable to nonresponse because of the difficult nature of accessing heavy drug users. However, in a study that matched 1990 census data to 1990 NHSDA nonrespondents,¹³ it was found that populations with low response rates did not always have high drug use rates. For example, although some populations were found to have low response rates and high drug use rates (e.g., residents of large metropolitan areas and males), other populations had low response rates and low drug use rates (e.g., older adults and high-income populations). Therefore, many of the potential sources of bias tend to cancel each other in estimates of overall prevalence (Gfroerer, Lessler, & Parsley, 1997a).

B.3.2 Inconsistent Responses and Item Nonresponse

Among survey participants, item response rates were generally very high for most drug use items. However, respondents could give inconclusive or inconsistent information about

¹² The usable case rule requires that a respondent answer "yes" or "no" to the question on lifetime use of cigarettes and "yes" or "no" to at least nine additional lifetime use questions.

¹³ Prior to 2002, NSDUH was known as the National Household Survey on Drug Abuse (NHSDA).

whether they ever used a given drug (i.e., "yes" or "no") and, if they had used a drug, when they last used it; the latter information is needed to identify those lifetime users of a drug who used it in the past year or past month. In addition, respondents could give inconsistent responses to items such as when they first used a drug compared with their most recent use of a drug. These missing or inconsistent responses first are resolved where possible through a logical editing process. Additionally, missing or inconsistent responses are imputed using statistical methodology. These imputation procedures in NSDUH are based on responses to multiple questions, so that the maximum amount of information is used in determining whether a respondent is classified as a user or nonuser, and if the respondent is classified as a user, whether the respondent is classified as having used in the past year or the past month. For example, ambiguous data on the most recent use of cocaine are statistically imputed based on a respondent's data for use (or most recent use) of tobacco products, alcohol, inhalants, marijuana, hallucinogens, and nonmedical use of prescription psychotherapeutic drugs. Nevertheless, editing and imputation of missing responses are potential sources of measurement error. For more information on editing and statistical imputation, see Sections A.3.1 and A.3.2 of Appendix A. Details of the editing and imputation procedures for 2011 also will appear in the *2011 NSDUH Methodological Resource Book*, which is in process. Until that volume becomes available, refer to the *2010 NSDUH Methodological Resource Book* (RTI International, 2012).

B.3.3 Data Reliability

A reliability study was conducted as part of the 2006 NSDUH to assess the reliability of responses to the NSDUH questionnaire. An interview/reinterview method was employed in which 3,136 individuals were interviewed on two occasions during 2006 generally 5 to 15 days apart; the initial interviews in the reliability study were a subset of the main study interviews. The reliability of the responses was assessed by comparing the responses of the first interview with the responses from the reinterview. Responses from the first interview and reinterview that were analyzed for response consistency were raw data that had been only minimally edited for ease of analysis and had not been imputed (see Sections A.3.1 and A.3.2 in this report).

This section summarizes the results for the reliability of selected variables related to substance use and demographic characteristics. Reliability is expressed by estimates of Cohen's kappa (κ) (Cohen, 1960), which can be interpreted according to benchmarks proposed by Landis and Koch (1977, p. 165): (a) *poor* agreement for kappas less than 0.00, (b) *slight* agreement for kappas of 0.00 to 0.20, (c) *fair* agreement for kappas of 0.21 to 0.40, (d) *moderate* agreement for kappas of 0.41 to 0.60, (e) *substantial* agreement for kappas of 0.61 to 0.80, and (f) *almost perfect* agreement for kappas of 0.81 to 1.00.

The kappa values for the lifetime and past year substance use variables (marijuana use, alcohol use, and cigarette use) all showed almost perfect response consistency, ranging from 0.82 for past year marijuana use to 0.93 for lifetime marijuana use and past year cigarette use. The value obtained for the substance dependence or abuse measure in the past year showed substantial agreement (0.67), while the substance abuse treatment variable showed almost perfect consistency in both the lifetime (0.89) and past year (0.87). The variables for age at first use of marijuana and perceived great risk of smoking marijuana once a month showed substantial agreement (0.74 and 0.68, respectively). The demographic variables showed almost perfect agreement, ranging from 0.95 for current enrollment in school to 1.00 for gender. For further

information on the reliability of a wide range of measures contained in NSDUH, see the complete methodology report (Chromy et al., 2010).

B.3.4 Validity of Self-Reported Substance Use

Most substance use prevalence estimates, including those produced for NSDUH, are based on self-reports of use. Although studies generally have supported the validity of self-report data, it is well documented that these data may be biased (underreported or overreported). The bias varies by several factors, including the mode of administration, the setting, the population under investigation, and the type of drug (Aquilino, 1994; Brener et al., 2006; Harrison & Hughes, 1997; Tourangeau & Smith, 1996; Turner, Lessler, & Gfroerer, 1992). NSDUH utilizes widely accepted methodological practices for increasing the accuracy of self-reports, such as encouraging privacy through audio computer-assisted self-interviewing (ACASI) and providing assurances that individual responses will remain confidential. Comparisons using these methods within NSDUH have shown that they reduce reporting bias (Gfroerer, Eyerman, & Chromy, 2002). Various procedures have been used to validate self-report data, such as biological specimens (e.g., urine, hair, saliva), proxy reports (e.g., family member, peer), and repeated measures (e.g., recanting) (Fendrich, Johnson, Sudman, Wislar, & Spiehler, 1999). However, these procedures often are impractical or too costly for general population epidemiological studies (SRNT Subcommittee on Biochemical Verification, 2002).

A study cosponsored by the Substance Abuse and Mental Health Services Administration (SAMHSA) and the National Institute on Drug Abuse (NIDA) examined the validity of NSDUH self-report data on drug use among persons aged 12 to 25. The study found that it is possible to collect urine and hair specimens with a relatively high response rate in a general population survey, and that most youths and young adults reported their recent drug use accurately in self-reports (Harrison, Martin, Enev, & Harrington, 2007). However, there were some reporting differences in either direction, with some respondents not reporting use but testing positive, and some reporting use but testing negative. Technical and statistical problems related to the hair tests precluded presenting comparisons of self-reports and hair test results, while small sample sizes for self-reports and positive urine test results for opiates and stimulants precluded drawing conclusions about the validity of self-reports of these drugs. Further, inexactness in the window of detection for drugs in biological specimens and biological factors affecting the window of detection could account for some inconsistency between self-reports and urine test results.

B.3.5 Revised Estimates for 2006 to 2010

During regular data collection and processing checks for the 2011 NSDUH, data errors were identified. These errors resulted from fraudulent cases submitted by field interviewers and affected the data for Pennsylvania (2006 to 2010) and Maryland (2008 and 2009). Although all fraudulent interview cases were removed from the data files, the affected screening cases were not removed because they were part of the assigned sample. Instead, these screening cases were assigned a final screening code of 39 ("Fraudulent Case") and treated as incomplete with unknown eligibility. The screening eligibility status for these cases then was imputed. Those cases that were imputed to be eligible were treated as unit nonrespondents for weighting purposes; however, these cases were not treated differently from other unit nonrespondents in the weighting process (see Section A.3.3 in Appendix A). In Table B.3, cases that were imputed to

be eligible are classified with a final code of 39 ("Fraudulent Case"). The cases that were imputed to be ineligible did not contribute to the weights and are reported as "Other, Ineligible" in Table B.3. Because all of these cases were treated either as ineligible or as unit nonrespondents at the screening level, they were excluded from the interview data in Table B.4. However, some estimates for 2006 to 2010 in the 2011 national findings report and the 2011 detailed tables, as well as other new reports, may differ from corresponding estimates found in some previous reports or tables.

These errors had minimal impact on the national estimates and no effect on direct estimates for the other 48 States and the District of Columbia. In reports where model-based small area estimation techniques are used, estimates for all States may be affected, even though the errors were concentrated in only two States. In reports that do not use model-based estimates, the only estimates appreciably affected are estimates for Pennsylvania, Maryland, the mid-Atlantic division, and the Northeast region.

The 2011 national findings report and detailed tables do not include State-level or model-based estimates. However, they do include estimates for the mid-Atlantic division and the Northeast region. Single-year estimates based on 2006 to 2010 data and pooled 2008 and 2009 data may differ from previously published estimates. Tables and estimates based only on 2011 data are unaffected by these data errors.

Caution is advised when comparing data from older reports with data from more recent reports that are based on corrected data files. As discussed above, comparisons of estimates for Pennsylvania, Maryland, the mid-Atlantic division, and the Northeast region are of most concern, while comparisons of national data or data for other States and regions are essentially still valid. CBHSQ within SAMHSA is producing a selected set of corrected versions of reports and tables. In particular, CBHSQ has released a set of modified detailed tables that include revised 2006 to 2010 estimates for the mid-Atlantic division and the Northeast region for certain key measures. CBHSQ does not recommend making comparisons between unrevised 2006 to 2010 estimates and estimates based on 2011 data for the geographic areas of greatest concern.

B.4 Measurement Issues

B.4.1 Incidence

In epidemiological studies, incidence is defined as the number of new cases of a disease occurring within a specific period of time. Similarly, in substance use studies, incidence refers to the first use of a particular substance.

In the 2004 NSDUH national findings report (Office of Applied Studies [OAS], 2005), a new measure related to incidence was introduced and since then has become the primary focus of Chapter 5 in this national findings report series. The incidence measure is termed as "past year initiation" and refers to respondents whose date of first use of a substance was within the 12 months prior to their interview date. This measure is determined by self-reported past year use, age at first use, year and month of recent new use, and the interview date.

Since 1999, the survey questionnaire has allowed for collection of year and month of first use for recent initiates (i.e., persons who used a particular substance for the first time in a given survey year). Month, day, and year of birth also are obtained directly or are imputed for item nonrespondents as part of the data postprocessing. Additionally, the computer-assisted interviewing (CAI) instrument records and provides the date of the interview. By imputing a day of first use within the year and month of first use, a specific date of first use, $t_{fu,d,i}$, can be used for estimation purposes.

Past year initiation among persons using a substance in the past year can be viewed as an indicator variable defined as follows:

$$I_{(Past\ Year\ Initiate)}(i) = \begin{cases} 1 & \text{if } (DOI_i MOI_i YOI_i - t_{fu,d,i}) \leq 365 \\ 0 & \text{otherwise} \end{cases},$$

where DOI_i , MOI_i , and YOI_i denote the day, month, and year of the interview, respectively, and $t_{fu,d,i}$ denotes the date of first use.

The calculation of this estimate does not take into account whether a respondent initiated substance use while a resident of the United States. This method of calculation has little effect on past year estimates and allows for direct comparability with other standard measures of substance use because the populations of interest for the measures will be the same (i.e., both measures examine all possible respondents and are not restricted to those initiating substance use only in the United States).

One important note for incidence estimates is the relationship between main categories and subcategories of substances (e.g., illicit drugs would be a main category, and inhalants and marijuana would be subcategories in relation to illicit drugs). For most measures of substance use, any member of a subcategory is by necessity a member of the main category (e.g., if a respondent is a past month user of a particular drug, then he or she is also a past month user of illicit drugs in general). However, this is not the case with regard to incidence statistics. Because an individual can only be an initiate of a particular substance category (main or sub) a single time, a respondent with lifetime use of multiple substances may not, by necessity, be included as a past year initiate of a main category, even if he or she were a past year initiate for a particular subcategory because his or her first initiation of other substances within the main category could have occurred earlier.

In addition to estimates of the number of persons initiating use of a substance in the past year, estimates of the mean age of past year initiates of these substances are computed. Unless specified otherwise, estimates of the mean age at initiation in the past 12 months have been restricted to persons aged 12 to 49 so that the mean age estimates reported are not influenced by those few respondents who were past year initiates and were aged 50 or older. As a measure of central tendency, means are influenced heavily by the presence of extreme values in the data, and this constraint should increase the utility of these results to health researchers and analysts by providing a better picture of the substance use initiation behaviors among the civilian, noninstitutionalized population in the United States. This constraint was applied only to

estimates of mean age at first use and does not affect estimates of the numbers of new users or the incidence rates.

Although past year initiates aged 26 to 49 are assumed not to be as likely as past year initiates aged 50 or older to influence mean ages at first use, caution still is advised in interpreting trends in these means. For example, the estimate of 49,000 persons aged 26 to 49 who were past year initiates of marijuana in 2009 was significantly different from the estimate of 138,000 past year initiates in this age group in 2011 (Table B.6). However, the estimate of 210,000 past year marijuana initiates aged 26 to 49 in 2010 was not significantly different from the number in 2011. In addition, the mean age at first use of marijuana among past year marijuana initiates aged 26 to 49 was higher in 2010 than in 2011, but the mean ages at first use among past year initiates in this age group were similar between 2011 and other years (Table B.7).

Because NSDUH is a survey of persons aged 12 years old or older at the time of the interview, younger individuals in the sample dwelling units are not eligible for selection into the NSDUH sample. Some of these younger persons may have initiated substance use during the past year. As a result, past year initiate estimates suffer from undercoverage if a reader assumes that these estimates reflect all initial users instead of only for those above the age of 11. For earlier years, data can be obtained retrospectively based on the age at and date of first use. As an example, persons who were 12 years old on the date of their interview in the 2011 survey may report having initiated use of cigarettes between 1 and 2 years ago; these persons would have been past year initiates reported in the 2010 survey had persons who were 11 years old on the date of the 2010 interview been allowed to participate in the survey. Similarly, estimates of past year use by younger persons (age 10 or younger) can be derived from the current survey, but they apply to initiation in prior years and not the survey year.

To get an impression of the potential undercoverage in the current year, reports of substance use initiation reported by persons aged 12 or older were estimated for the years in which these persons would have been 1 to 11 years younger. These estimates do not necessarily reflect behavior by persons 1 to 11 years younger in the current survey. Instead, the data for the 11 year olds reflect initiation in the year prior to the current survey, the data for the 10 year olds reflect behavior between the 12th and 23rd months prior to this year's survey, and so on. A very rough way to adjust for the difference in the years that the estimate pertains to without considering changes in the population is to apply an adjustment factor to each age-based estimate of past year initiates. This adjustment factor can be based on a ratio of lifetime users aged 12 to 17 in the current survey year to the same estimate for the prior applicable survey year. To illustrate the calculation, consider past year use of alcohol. In the 2011 survey, 75,681 persons 12 years old were estimated to have initiated use of alcohol between 1 and 2 years earlier. These persons would have been past year initiates in the 2010 survey conducted on the same dates had the 2010 survey covered younger persons. The estimated number of lifetime users currently aged 12 to 17 was 8,610,370 for 2011 and 8,621,883 for 2010, indicating fewer overall initiates of alcohol use among persons aged 17 or younger in 2011. Thus, an adjusted estimate of initiation of alcohol use by persons who were 11 years old in 2011 is given by

$$(\text{Estimated Past Year Initiates Aged 11})_{2010} \times \frac{(\text{Estimated Lifetime Users Aged 12 to 17})_{2011}}{(\text{Estimated Lifetime Users Aged 12 to 17})_{2010}} .$$

This yielded an adjusted estimate of 75,580 persons 11 years old on a 2011 survey date and initiating use of alcohol in the past year:

$$75,681 \times \frac{8,610,370}{8,621,883} = 75,580 .$$

A similar procedure was used to adjust the estimated number of past year initiates among persons who would have been 10 years old on the date of the interview in 2009 and for younger persons in earlier years. The overall adjusted estimate for past year initiates of alcohol use by persons 11 years of age or younger on the date of the interview was 163,428, or about 3.5 percent of the estimate based on past year initiation by persons 12 or older only ($163,428 \div 4,699,084 = 0.0348$). Based on similar analyses, the estimated undercoverage of past year initiates was 3.1 percent for cigarettes, 0.7 percent for marijuana, and 17.0 percent for inhalants.

The undercoverage of past year initiates aged 11 or younger also affects the mean age at first use estimate. An adjusted estimate of the mean age at first use was calculated using a weighted estimate of the mean age at first use based on the current survey and the numbers of persons aged 11 or younger in the past year obtained in the aforementioned analysis for estimating undercoverage of past year initiates. Analysis results showed that the mean age at first use was changed from 17.1 to 16.8 for alcohol, from 17.2 to 16.9 for cigarettes, from 17.5 to 17.4 for marijuana, and from 16.4 to 15.1 for inhalants. The decreases reported above are comparable with results generated in prior survey years.

B.4.2 Illicit Drug and Alcohol Dependence and Abuse

The 2011 NSDUH CAI instrumentation included questions that were designed to measure alcohol and illicit drug dependence and abuse. For these substances,¹⁴ dependence and abuse questions were based on the criteria in the *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition (DSM-IV) (American Psychiatric Association [APA], 1994). Specifically, for marijuana, hallucinogens, inhalants, and tranquilizers, a respondent was defined as having dependence if he or she met three or more of the following six dependence criteria:

1. Spent a great deal of time over a period of a month getting, using, or getting over the effects of the substance.
2. Used the substance more often than intended or was unable to keep set limits on the substance use.
3. Needed to use the substance more than before to get desired effects or noticed that the same amount of substance use had less effect than before.

¹⁴ Substances include alcohol, marijuana, cocaine, heroin, hallucinogens, inhalants, pain relievers, tranquilizers, stimulants, and sedatives.

4. Inability to cut down or stop using the substance every time tried or wanted to.
5. Continued to use the substance even though it was causing problems with emotions, nerves, mental health, or physical problems.
6. The substance use reduced or eliminated involvement or participation in important activities.

For alcohol, cocaine, heroin, pain relievers, sedatives, and stimulants, a seventh withdrawal criterion was added. A respondent was defined as having dependence if he or she met three or more of seven dependence criteria. The seventh withdrawal criterion is defined by a respondent reporting having experienced a certain number of withdrawal symptoms that vary by substance (e.g., having trouble sleeping, cramps, hands tremble).

For each illicit drug and alcohol, a respondent was defined as having abused that substance if he or she met one or more of the following four abuse criteria and was determined not to be dependent on the respective substance in the past year:

1. Serious problems at home, work, or school caused by the substance, such as neglecting your children, missing work or school, doing a poor job at work or school, or losing a job or dropping out of school.
2. Used the substance regularly and then did something that might have put you in physical danger.
3. Use of the substance caused you to do things that repeatedly got you in trouble with the law.
4. Had problems with family or friends that were probably caused by using the substance and continued to use the substance even though you thought the substance use caused these problems.

Criteria used to determine whether a respondent was asked the dependence and abuse questions during the interview included responses from the core substance use questions and the frequency of substance use questions, as well as the noncore substance use questions. Missing or incomplete responses in the core substance use and frequency of substance use questions were imputed. However, the imputation process did not take into account reported data in the noncore (i.e., substance dependence and abuse) CAI modules. Very infrequently, this may result in responses to the dependence and abuse questions that were inconsistent with the imputed substance use or frequency of substance use.

For alcohol and marijuana, respondents were asked the dependence and abuse questions if they reported substance use on more than 5 days in the past year, or if they reported any substance use in the past year but did not report their frequency of past year use. Therefore, inconsistencies could have occurred where the imputed frequency of use response indicated less frequent use than required for respondents to be asked the dependence and abuse questions originally. For alcohol, for example, about 42,000 respondents were past year alcohol users in 2011. Of these, fewer than 100 respondents (about 0.2 percent) were asked the alcohol dependence and abuse questions, but their final imputed frequency of use indicated that they used alcohol on 5 or fewer days in the past year.

For cocaine, heroin, and stimulants, respondents were asked the dependence and abuse questions if they reported past year use in a core drug module or past year use in the noncore special drugs module. Thus, the CAI logic allowed some respondents to be asked the dependence and abuse questions for these drugs even if they did not report past year use in the corresponding core module. For cocaine, for example, more than 1,500 respondents in 2011 were asked the questions about cocaine dependence and abuse because they reported past year use of cocaine or crack in the core section of the interview. Fewer than 10 additional respondents were asked these questions because they reported past year use of cocaine with a needle in the special drugs module despite not having previously reported past year use of cocaine or crack.

In 2005, two new questions were added to the noncore special drugs module about past year methamphetamine use: "Have you ever, even once, used methamphetamine?" and "Have you ever, even once, used a needle to inject methamphetamine?" In 2006, an additional follow-up question was added to the noncore special drugs module confirming prior responses about methamphetamine use: "Earlier, the computer recorded that you have never used methamphetamine. Which answer is correct?" The responses to these new questions were used in the skip logic for the stimulant dependence and abuse questions. Based on the decisions made during the methamphetamine analysis,¹⁵ respondents who indicated past year methamphetamine use solely from these new special drug use questions (i.e., did not indicate methamphetamine use from the core drug module or other questions in the special drugs module) were categorized as NOT having past year stimulant dependence or abuse regardless of how they answered the dependence and abuse questions. Furthermore, if these same respondents were categorized as not having past year dependence or abuse of any other substance (e.g., pain relievers, tranquilizers, or sedatives for the psychotherapeutic drug grouping), then they were categorized as NOT having past year dependence or abuse of psychotherapeutics, illicit drugs, illicit drugs or alcohol, and illicit drugs and alcohol.

In 2008, questionnaire logic for determining hallucinogen, stimulant, and sedative dependence or abuse was modified. The revised skip logic used information collected in the noncore special drugs module in addition to that collected in questions from the core drug modules. Respondents were asked about hallucinogen dependence and abuse if they additionally reported in the special drugs module using Ketamine, DMT, AMT, Foxy, or *Salvia divinorum*; stimulant dependence and abuse if they reported additionally using Adderall[®]; and sedative dependence and abuse if they reported additionally using Ambien[®]. Complying with the previous decision to exclude respondents whose methamphetamine use was based solely on responses in a noncore module from being classified as having stimulant dependence or abuse, respondents who indicated past year hallucinogen, stimulant, or sedative use based solely on these special drug questions were categorized as NOT having past year dependence or abuse of the relevant substance regardless of how they answered the dependence and abuse questions.

Respondents might have provided ambiguous information about past year use of any individual substance, in which case these respondents were not asked the dependence and abuse questions for that substance. Subsequently, these respondents could have been imputed to be past year users of the respective substance. In this situation, the dependence and abuse data were

¹⁵ See Section B.4.8 in the *Results from the 2008 National Survey on Drug Use and Health: National Findings* (OAS, 2009) for the methamphetamine analysis decisions.

unknown; thus, these respondents were classified as not having dependence or abuse of the respective substance. However, such a respondent never actually was asked the dependence and abuse questions.

B.4.3 Impact of Decennial Census Effects on NSDUH Substance Use Estimates

As discussed in Section A.3.3 in Appendix A, the person-level weights in NSDUH were calibrated to population estimates (or control totals) obtained from the U.S. Census Bureau. For the weights in 2002 through 2010, annually updated control totals based on the 2000 census were used. Beginning with the 2011 weights, however, the control totals from the Census Bureau were based on the 2010 census. As a result, there was a possibility that the change from the 2000 to the 2010 census as the basis for updating NSDUH control totals could result in demographic and geographic shifts in the U.S. population that were not accounted for in population estimates that were made during the period between the censuses (i.e., in the annually updated 2000 census-based control totals provided by the Census Bureau for the years 2002 to 2010). This is because for the years between each decennial census, the Census Bureau produces annual national-level postcensal population estimates, based on the most recent census data, applying adjustments to account for births to U.S.-resident women, deaths of U.S. residents, and net international migration.¹⁶ With this estimation method, the postcensal estimates made for the years immediately following a census are likely to be the most accurate (e.g., 2002 postcensal estimates are expected to be more accurate than 2009 postcensal estimates). Therefore, the population control totals for 2010 based on the 2010 census, provided specifically for this study by the Census Bureau to SAMHSA, would presumably represent the characteristics of the population more accurately than the projections for 2010 that were based on the 2000 census. For NSDUH estimation purposes, the first set of control totals that incorporated data from the 2010 census for the regular NSDUH weighting processes was the 2011 control totals.

Table B.8 shows the estimated numbers of persons for the civilian, noninstitutionalized population aged 12 or older in 2010 based on both the 2000 census and the 2010 census. Overall, the estimated numbers for the 2010 population based on the 2000 census were similar to the 2010 census-based population characteristics, with a difference of less than 1 percent (0.7 percent). Larger differences were observed in several domains for race (e.g., American Indians or Alaska Natives, Native Hawaiians or Other Pacific Islanders, and persons reporting two or more races).¹⁷

Methods for Assessing Census Effects on Substance Use Estimates. For the 9-month period from April through December 2010, the Census Bureau produced control totals based on both the 2000 and 2010 censuses. To assess the decennial census effect on NSDUH estimates of substance use, the person-level poststratification adjustment also was done for the 2010 NSDUH respondents using the 2010 census-based control totals, leading to the creation of a second set of analysis weights for 2010. In order for analysis weights to be produced that reflect the entire year, the population estimates for the first quarter of 2010 were projected, and the annualized numbers were used in the poststratification adjustment. Therefore, there now were two sets of

¹⁶ For details on how the Census Bureau creates the postcensal estimates, see <http://www.census.gov/popest/methodology/2011-nat-st-co-meth.pdf>.

¹⁷ Unlike racial/ethnic groups discussed elsewhere in this report, race domains in this section include Hispanics in addition to persons who were not Hispanic.

weights for 2010: one based on the 2000 census and one based on the 2010 census. This evaluation was based on the premise that any difference between estimates based on these two weights could solely be attributed to the "census effect" because the underlying data were the same.

Estimates from 44 selected substance use tables that included estimated numbers, percentages, and mean ages at initiation were used to examine the effects on estimates in 2010 when weights were based on the 2010 census control totals compared with when weights were based on the 2000 census control totals. These tables are available at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.¹⁸

In these tables, estimates for 2011 used weights that were poststratified to 2011 control totals based on the 2010 census. The following terms also were defined in the tables for estimates in 2010:

- *2010 (Old)*: estimates for 2010 with weights poststratified to 2010 control totals based on the 2000 census; and
- *2010 (New)*: estimates for 2010 with weights poststratified to 2010 control totals based on the 2010 census.

The estimates referred to as "2010 (Old)" represent the official NSDUH estimates for 2010.¹⁹

To assess the census effect, significance testing was conducted between 2011 and 2010 (Old) and between 2011 and 2010 (New). This evaluation examined whether differences between estimates for 2011 and those in 2010 would be significant (or not significant) depending on whether the estimates for 2010 were based on the control totals from the 2000 census or the 2010 census. Ideally, the change in control totals would not affect whether differences between 2010 and 2011 were statistically significant.

Results. Comparisons of the results of the significance tests between estimates for 2011 and corresponding estimates for 2010 that were based on population control totals from the 2010 census agreed over 94 percent of the time with results of comparisons between the 2011 estimates and those for 2010 that were based on population control totals from the 2000 census. In general, use of 2010 census control totals for the 2010 estimates had more of an impact on the estimated numbers of substance users than on the percentages. Estimates of the numbers of substance users were notably affected for American Indians or Alaska Natives and persons reporting two or more races. This impact of the 2010 census-based control totals on these subgroups is consistent with the data from Table B.8 indicating that these were the subgroups that saw the largest shifts in population totals. Hence, some caution is needed for interpreting differences between 2011 and NSDUH estimates for 2010 that are presented in this report and in

¹⁸ Additional tables for perceived risk associated with substance use, need for and receipt of treatment, and driving under the influence of alcohol or other drugs also are available at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>, but they are not discussed in this section.

¹⁹ Some 2010 (Old) estimates may differ from previously published estimates due to updates (see Section B.3).

the 2011 detailed tables, especially for estimated numbers of users, including those in the two racial/ethnic groups mentioned previously.

Table B.9 summarizes the results of 1,002 tests of statistical significance at the .05 level of significance across the 44 tables of estimates mentioned previously. Table B.9 does not include the results of 26 tests in which some estimates were suppressed because of low precision (see Section B.2.2). As noted previously, most of the differences between estimates for 2011 and 2010 (Old) and between estimates for 2011 and 2010 (New) were in agreement (947 tests or 94.5 percent of all tests); that is, statistical tests of the difference between 2011 and 2010 (Old) and tests of the difference between 2011 and 2010 (New) both were significant, or both were not significant at .05 level. There were no situations identified in which results of comparisons of mean ages at first use between 2011 and 2010 disagreed according to whether 2010 (Old) or 2010 (New) estimates were used among the 66 tests for this measure.

For 49 tests (4.9 percent), the difference between 2011 and 2010 (Old) was significant, but the difference between 2011 and 2010 (New) was not. Among these 49 tests, the majority (i.e., 30) involved situations in which the estimated number of users was significantly different between 2011 and the 2010 (Old) estimates, but the difference for 2011 versus 2010 (New) was not significant. For the remaining 19 situations, the disagreement involved estimated percentages who were users.

Of the 30 tests in which the estimated number of users was significantly different between 2011 and the 2010 (Old) estimates but the difference for 2011 versus 2010 (New) was not, 19 (or over half) were from the race/ethnicity domain. In particular, seven of these were for the estimated numbers of users among persons reporting two or more races.²⁰ For example, there was a statistically significant 35 percent increase in the estimated number of past month illicit drug users reporting two or more races when the estimate for 2011 was compared with 2010 (Old). When this estimate for 2011 was compared with the corresponding estimate for 2010 (New), however, the number changed by less than 7 percent, and the difference was not statistically significant. This effect was observed for the estimated numbers of past month illicit drug users, but not for the percentages of past month drug users reporting two or more races; differences in the percentages were not significant between 2011 and 2010 (Old) or between 2011 and 2010 (New). Similar results were observed for past month use of cigarettes and alcohol for this subgroup. In addition, the estimated number of past month alcohol users who were American Indians or Alaska Natives increased by 45 percent from 2010 to 2011 based on the 2010 (Old) estimate, but did not differ significantly between 2010 and 2011 based on the 2010 (New) estimate; differences in the percentages were not significant between 2011 and 2010 (Old) or between 2011 and 2010 (New).

Among the 19 tests in which the percentages differed between 2011 and 2010 (Old) but the percentages between 2011 and 2010 (New) were not significantly different, 7 tests also came from the race/ethnicity domain. The domains primarily affected by the change in population data from the 2000 to the 2010 censuses appear to be persons reporting two or more races and persons who were American Indians or Alaska Natives.

²⁰ See Tables 1.5A, 1.7A, 1.8A, and 1.11A at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

For six tests (all involving estimated numbers of users), the difference between 2011 and 2010 (Old) was not significant, but the difference would have been significant if the 2010 (New) estimate had been reported for 2010. Of these six tests, five involved age groups, including four that affected the numbers of youths aged 12 to 17 who were estimated to be lifetime users of cigarettes or inhalants, nonmedical users of pain relievers, or users of illicit drugs other than marijuana.²¹ There were no tests involving percentages where the difference between 2011 and 2010 (Old) was not significant, but the difference would have been significant if the 2010 (New) estimate had been reported for 2010.

Table B.10 shows comparisons of tests of significance in the differences between 2011 and 2010 (New) and between 2011 and 2010 (Old). These comparisons take into account the direction of the difference between 2011 and 2010: (a) the 2011 estimate decreased from the 2010 estimate; (b) there was no difference between 2011 and 2010; and (c) the 2011 estimate increased from the 2010 estimate. The majority of the off-diagonal elements (i.e., where there was disagreement between the two differences) occurred in situations where there was a decrease in prevalence from 2010 to 2011 based on the 2010 (Old) estimate, but there was no difference between 2010 and 2011 based on 2010 (New) estimate (32 tests). There were 17 tests where there was a reported increase between 2010 and 2011 based on the 2010 (Old) estimate, but the difference would not have been significant if the weights for the 2010 estimate had been based on control totals from the 2010 census.

For the 2010 estimates, about 70 percent of the 2010 (New) estimates were lower than the 2010 (Old) estimates in the 44 tables that were examined. As shown in Table B.8, more persons in 2010 were estimated to be aged 12 to 17, female, and Hispanic, and fewer persons were estimated to be white based on the 2010 census control totals than on the 2000 census projections. As noted elsewhere in this report, substance use prevalence rates in 2011 were lower among youths aged 12 to 17 than among young adults aged 18 to 25 and were lower among females than males. In addition, whites in 2011 were more likely than persons in other racial/ethnic groups to be current alcohol users. Among youths and young adults in 2011, current cigarette smoking was more prevalent among whites than blacks. Consequently, population shifts between 2000 and 2010 that led to an increase in the population for demographic groups that are less likely to be substance users could affect substance use estimates according to the census on which the population control totals for analysis weights were based.

Conclusions. Due to changes in population sizes with the 2011 data based on the 2010 census control totals, especially for particular subgroups (e.g., persons reporting two or more races), caution is advised when comparing differences in estimated numbers between 2011 and prior years. Although the impact of the population changes is smaller for estimated percentages than for numbers of persons, some caution also is advised when comparing percentages between 2011 and prior years. There were only 19 instances where the difference between 2011 and 2010 (Old) percentages was significant but the difference between 2011 and 2010 (New) was not significantly different. However, the general result is that the 2010 (New) percentages for most estimates are lower than the 2010 (Old) estimates. The implication is that the 2011 estimates (percentages) may have been higher if weights based on the 2000 census had been used. As a result, downward trends involving 2011 data may be slightly overstated, and upward trends may

²¹ See Tables 1.2A and 1.7A at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

be slightly understated. Therefore, if affected 2011 data show an upward trend, then in most cases, confidence can be placed in that trend. If the 2011 data show a decreasing trend, then less confidence can be placed in it. There are a few exceptions (e.g., for 12 to 17 year olds) that are discussed below.

However, as discussed earlier, the postcensal population estimates that define the control totals are not without error, and the effect on NSDUH estimates and trends due to the change from 2000-based to 2010-based control totals would be greatest for 2010 NSDUH estimates and for estimates for years closest to 2010. Conversely, the effect would be expected to be lowest for NSDUH estimates in years farthest from 2010 (e.g., 2002). As stated previously, less confidence might be placed in downward trends in some rates following the change to 2010 census-based control totals in 2011 because the new control totals tended to reduce those rates. Conversely, less confidence should also be placed on results showing increases in the numbers of substance users because the new control totals generally reflect a population increase. Nevertheless, given that the census effect would be greatest for 2010 estimates, findings of similar differences between 2011 and 2010 (regardless of whether 2010 estimates were based on 2000 or 2010 census control totals) can provide another indicator of the basic validity of the trend data.

Estimates for 12 to 17 and 12 to 20 Year Olds

For youths aged 12 to 17, the estimated numbers of lifetime and past month illicit drug, alcohol, and cigarette users showed results counter to those for the overall population aged 12 or older. Altogether, there were four comparisons for youths²² where the 2010 (New) and 2011 estimates were significantly different, but the 2010 (Old) and 2011 estimates were not. In addition, for all lifetime and most past month numbers of users, the 2010 (New) estimate was larger than the 2010 (Old) estimate. This would suggest that some trends in the estimated numbers of illicit drug, cigarette, and alcohol users for 12 to 17 year olds between previous years and 2011 may overstate increases and understate decreases. Therefore, if the estimated numbers of illicit drug, cigarette, and alcohol users in 2011 showed a downward trend, then confidence can be placed in these trends in most instances. However, if the numbers of illicit drug, cigarette, and alcohol users in 2011 showed an increasing trend, then less confidence can be placed in the trend. Rates of lifetime and past month use of illicit drugs and cigarettes for 12 to 17 year olds appeared to be unaffected by the use of 2010 census-based control totals.²³

However, for overall and subgroup estimates of underage drinking among persons aged 12 to 20 (i.e., past month alcohol use, binge alcohol use, and heavy alcohol use) the 2010 (New) estimates tended to be lower than the 2010 (Old) estimates.²⁴ In some situations, this resulted in the 2010 (Old) and 2011 estimates being significantly different, but the 2010 (New) and 2011 estimates were not. Therefore, the use of 2010 census-based control totals in 2011 may overstate some decreases in underage drinking between previous years and 2011.

²² See Tables 1.2A and 1.7A at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

²³ See Tables 1.2B and 1.7B at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

²⁴ See Tables 1.11B, 1.12B, and 1.13B at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

Estimates for 18 to 25 Year Olds

Overall rates of use of illicit drugs, cigarettes, and alcohol for young adults aged 18 to 25 appeared to be affected by the changes in weights.²⁵ Most 2010 (New) estimates for the rates of use of different types of drugs, cigarettes, or alcohol were slightly lower than (but still significantly different from) the 2010 (Old) estimates. Again, this would imply that caution should be applied when interpreting some differences in illicit drug, alcohol, and cigarette use estimates between 2011 and previous years because of the risk of overstating decreases and understating increases in 2011. Despite these caveats, the comparisons just between 2010 and 2011 appear to be valid for estimates of past month use among young adults because there were no situations where the use the 2010 (Old) and 2010 (New) data affected whether the difference between the 2010 and 2011 estimates was statistically significant.

Estimates for Persons Aged 26 or Older

Similar to the data for 18 to 25 year olds, the overall rates of illicit drug, cigarette, and alcohol use for persons aged 26 or older appeared to be affected by the use of 2010 census-based control totals.²⁶ Because the 2010 (New) estimates were likely to be lower than the 2010 (Old) estimates, the concern remains of overstating decreases and understating increases between 2011 and previous years. Despite these caveats, the comparisons of past month use just between 2010 and 2011 appeared to be valid for percentages among adults aged 26 or older because there were no situations in which using the 2010 (Old) or 2010 (New) estimates affected whether the difference between 2010 and 2011 was statistically significant.

Alcohol Use Estimates for Persons Aged 21 or Older

The overall rates of past month alcohol use, binge alcohol use, and heavy alcohol use among persons aged 21 or older were lower for the 2010 (New) estimates than for the 2010 (Old) estimates.²⁷ Subgroup differences based on gender and race/ethnicity were inconsistent, with some (but not all) showing significant differences between 2010 (Old) and 2010 (New) estimates. Therefore, comparisons of alcohol use by adults of legal drinking age by gender and race/ethnicity over time also should be made cautiously. Despite these caveats, the comparisons just between 2010 and 2011 appeared to be valid for estimated percentages of past month alcohol use, binge alcohol use, and heavy alcohol use among persons aged 21 or older because there was only one situation in which use of the 2010 (Old) or 2010 (New) data affected whether the difference between the 2010 and 2011 estimates was statistically significant.

Initiation Data

Of the 66 comparisons for the numbers of past year initiates that compared 2010 (Old) or 2010 (New) estimates with 2011 estimates overall and by drug and gender, only one comparison

²⁵ See Tables 1.3B, 1.7B, and 1.8B at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

²⁶ See Tables 1.4B, 1.7B, and 1.8B at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

²⁷ See Tables 1.14B, 1.15B, and 1.16B at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

was affected by whether the 2010 (Old) or 2010 (New) estimate was used.²⁸ This suggests that comparisons of initiation data by drug and gender are essentially valid between 2010 and 2011. There were statistically significant differences between the 2010 (Old) and 2010 (New) estimates, but these differences were not in any consistent direction. This suggests that for interpretation of initiation trends—especially for 2010 and years closest to 2010—the potential census effect for each drug should be considered separately.

Of the 66 comparisons that compared 2010 (Old) or 2010 (New) estimates of the mean age at first use with 2011 estimates overall and by drug and gender, none of the comparisons were affected by whether the 2010 (Old) or 2010 (New) estimate was used.²⁹ This suggests that comparisons of mean age at initiation data by drug and gender are valid between 2010 and 2011. However, 2010 (Old) mean age at initiation estimates were consistently lower than corresponding 2010 (New) estimates. This suggests that some trend data showing decreases in 2011 may be overstating the decrease in mean initiation age and may be underestimating any increases in mean age at initiation for most drugs.

Subgroup Data

As mentioned earlier in this report, this evaluation also examined the potential for census effects on different subgroups, such as by gender, race/ethnicity, geographic divisions, and county type. As discussed earlier, 7 of the 19 estimates where the percentages differed between 2011 and 2010 (Old) but were not significantly different between 2011 and 2010 (New) were for race/ethnicity. However, there was no single dominant subgroup within these 7 results. Also, even though the race/ethnicity comparisons comprised the largest portion of the 19 that differed according to whether 2011 estimates were compared with 2010 (Old) or 2010 (New), these 7 race/ethnicity comparisons comprised only a very small proportion (5.8 percent) of the total of 121 race/ethnicity comparisons that were performed.

The evaluation presented in this report focused specifically on measures of substance use that are used in the 2011 national findings report and detailed tables. A separate analysis is being conducted to evaluate the impact of the weighting changes on mental health estimates in the 2011 mental health national findings report and associated detailed tables. Details on that evaluation will be available in Appendix B of the 2011 mental health findings report.

In addition to the standard 2010 analysis weights developed for the 2010 public use file, special weights that were poststratified to 2010 control totals will be available on the 2010 NSDUH public use file in late 2012.

²⁸ See Tables 1.17A, 1.18A, and 1.19A at <http://www.samhsa.gov/data/NSDUH/NSDUHCensusEffects/Index.aspx>.

Table B.2 Summary of 2011 NSDUH Suppression Rules

Estimate	Suppress if:
Prevalence Rate, \hat{p} , with Nominal Sample Size, n , and Design Effect, $deff$ $\left(deff = \frac{n[SE(\hat{p})]^2}{\hat{p}(1-\hat{p})} \right)$	(1) The estimated prevalence rate, \hat{p} , is $< .00005$ or $\geq .99995$, or (2) $\frac{SE(\hat{p}) / \hat{p}}{-\ln(\hat{p})} > .175$ when $\hat{p} \leq .5$, or $\frac{SE(\hat{p}) / (1-\hat{p})}{-\ln(1-\hat{p})} > .175$ when $\hat{p} > .5$, or (3) <i>Effective</i> $n < 68$, where <i>Effective</i> $n = \frac{n}{deff} = \frac{\hat{p}(1-\hat{p})}{[SE(\hat{p})]^2}$, or (4) $n < 100$. Note: The rounding portion of this suppression rule for prevalence rates will produce some estimates that round at one decimal place to 0.0 or 100.0 percent but are not suppressed from the tables.
Estimated Number (Numerator of \hat{p})	The estimated prevalence rate, \hat{p} , is suppressed. Note: In some instances when \hat{p} is not suppressed, the estimated number may appear as a 0 in the tables. This means that the estimate is greater than 0 but less than 500 (estimated numbers are shown in thousands).
Mean Age at First Use, \bar{x} , with Nominal Sample Size, n	(1) $RSE(\bar{x}) > .5$, or (2) $n < 10$.

$deff$ = design effect; RSE = relative standard error; SE = standard error.

Appendix C: Other Sources of Data

There are sources of substance use data other than the National Survey on Drug Use and Health (NSDUH). It is useful to consider the results of these other studies when discussing NSDUH data because no single source of data can fully cover all issues associated with substance use in the United States. Each data source can contribute to a broader understanding of substance use and the relationships of substance use to other issues of interest. This appendix briefly describes several of these other data systems and presents selected comparisons with NSDUH results. In addition, this appendix describes surveys on substance use of populations not covered by NSDUH.

When evaluating the information presented here, it is important to consider and understand the methodological differences between the different surveys and the impact that these differences could have on estimates of the presence of substance use. Several studies have compared NSDUH estimates with estimates from other studies and have evaluated how differences may have been affected by differences in survey methodology (Gfroerer, Wright, & Kopstein, 1997b; Grucza, Abbacchi, Przybeck, & Gfroerer, 2007; Hennessy & Ginsberg, 2001; Miller et al., 2004). These comparisons suggest that the goals and approaches of surveys are often different, making comparisons between them difficult. Some methodological differences that have been identified as affecting comparisons include populations covered, sampling methods, modes of data collection, questionnaires, and estimation methods.

C.1 Other National Surveys of Substance Use

Behavioral Risk Factor Surveillance System (BRFSS)

The Behavioral Risk Factor Surveillance System (BRFSS)—a State-based system of health surveys—collects information on health risk behaviors, preventive health practices, and health care access primarily related to chronic disease and injury. The BRFSS surveys are cross-sectional telephone surveys conducted by State health departments with technical and methodological assistance from the Centers for Disease Control and Prevention (CDC). Every year, States conduct monthly telephone surveys of adults (aged 18 or older) in households using random-digit-dialing methods; persons living in group quarters (e.g., dormitories) are excluded. Since 1994, BRFSS has collected data from all 50 States, the District of Columbia, Puerto Rico, and the U.S. Virgin Islands using a computer-assisted telephone interviewing (CATI) design. More than 350,000 adults are interviewed each year. Beginning with the 2011 BRFSS, the sample design covers households using only cellular telephones. This change in coverage may affect estimates and comparability over time.

National estimates typically are presented as medians. BRFSS includes questions on alcohol consumption and tobacco use.

NSDUH and BRFSS rates of current alcohol use have been generally similar, but NSDUH has shown consistently higher rates of binge drinking than BRFSS. The use of audio computer-assisted self-interviewing (ACASI) in NSDUH, which is considered to be more anonymous and yields higher reporting of sensitive behaviors, was offered as an explanation for

the lower binge rates in BRFSS (Miller et al., 2004). Because BRFSS uses CATI, it may yield lower reports of some sensitive behaviors than NSDUH, which employs face-to-face data collection with ACASI for questions about these behaviors. Response rates also are higher in NSDUH than BRFSS, which could have resulted in differential nonresponse bias patterns in the two surveys.

For further details, see the CDC Web site at <http://www.cdc.gov/brfss/>.

Monitoring the Future (MTF)

The Monitoring the Future (MTF) study is an ongoing study of substance use trends and related attitudes among America's secondary school students, college students, and adults through age 50. The study is conducted annually by the Institute for Social Research at the University of Michigan through grants awarded by the National Institute on Drug Abuse (NIDA). The MTF and NSDUH are the Federal Government's largest and primary tools for tracking youth substance use. The MTF is composed of three substudies: (a) an annual survey of high school seniors initiated in 1975; (b) ongoing panel studies of representative samples from each graduating class (i.e., 12th graders) that have been conducted by mail since 1976; and (c) annual surveys of 8th and 10th graders initiated in 1991. Each spring, students in the 8th, 10th, and 12th grades complete a self-administered, machine-readable questionnaire during a regular class period. Approximately 50,000 students in about 420 public and private secondary schools are surveyed annually for the cross-sectional study, and approximately 2,400 persons who participated in the survey of 12th graders are followed longitudinally. The latest MTF was conducted in 2011. The MTF provides information on the use of alcohol, illicit drugs, and tobacco.

Comparisons between the MTF estimates and estimates based on students sampled in NSDUH generally have shown NSDUH substance use prevalence levels to be lower than MTF estimates (Table C.1).³⁰ The lower prevalences in NSDUH may be due to more underreporting in the household setting as compared with the MTF school setting and some overreporting in the school settings. However, findings presented in Chapter 8 of this report generally show parallel trends in the prevalence of substance use in NSDUH and MTF for both the annual cross-sectional data for youths and the longitudinal data for young adults.

The MTF does not survey dropouts or include students who were absent from school on the day of the survey. NSDUH has shown dropouts to have higher rates of illicit drug use (Gfroerer et al., 1997b). Therefore, the population of inference for the MTF school-based data collection is adolescents who were in the 8th, 10th, and 12th grades. Depending on the effects of the exclusion of dropouts and frequent absentees, data from MTF may not generalize to the population of adolescents as a whole, especially for older adolescents. The dropout rates among public school students in the 2008 to 2009 school year were 3.2 percent for 9th graders, 3.5 percent for 10th graders, 3.8 percent for 11th graders and 6.0 percent for 12th graders (Stillwell, Sable, & Plotts, 2011). Although these rates appear to be low, students dropping out of school in

³⁰ To examine estimates that are comparable with MTF data, NSDUH estimates presented in Table C.1 are based on data collected in the first 6 months of the survey year and are subset to ages 12 to 20.

each lower grade could have a cumulative effect on school-based survey estimates for adolescents in the higher grades.

For further details, see the MTF Web site at <http://www.monitoringthefuture.org/>.

National Comorbidity Survey (NCS)

The National Comorbidity Survey (NCS) was sponsored by the National Institute of Mental Health (NIMH), NIDA, and the W.T. Grant Foundation. It was designed to measure in the general population the prevalence of the illnesses described in the *Diagnostic and Statistical Manual of Mental Disorders*, 3rd edition revised (DSM-III-R) (American Psychiatric Association [APA], 1987). The first wave of the NCS was a household survey of persons in the continental United States (i.e., excluding Alaska and Hawaii) that collected data from 8,098 respondents aged 15 to 54 in a face-to-face interview using paper-and-pencil interviewing (PAPI). These responses were weighted to produce nationally representative estimates. A random sample of 4,414 respondents also was administered an additional module that captured information on nicotine dependence. The interviews took place between 1990 and 1992. The NCS used a modified version of the Composite International Diagnostic Interview (the University of Michigan-CIDI) to generate DSM-III-R diagnoses.

There have been several recent follow-ups to and replications of the original NCS, including a 10-year follow-up of the baseline sample (NCS-2), a replication study conducted in 2001 to 2003 with a newly recruited nationally representative sample of 9,282 respondents aged 18 or older (NCS-R) (Kessler et al., 2004), and an adolescent sample of adolescents aged 13 to 17 (NCS-A) in 2001 to 2004 that included 904 adolescents from households that participated in the NCS-R and 9,244 respondents from a nationally representative sample of 320 schools (Kessler et al., 2009). As for the NCS, the samples for the NCS-2, NCS-R, and NCS-A excluded Alaska and Hawaii.

The NCS provides information on the use of alcohol, illicit drugs, and tobacco and on substance dependence or abuse. The NCS-R used an updated version of the CIDI that was designed to capture diagnoses of substance abuse or dependence using current DSM-IV criteria (APA, 1994). Interviews were conducted using computer-assisted personal interviewing (CAPI). It should be noted that in several NCS-R studies (e.g., Kessler, Chiu, Demler, Merikangas, & Walters, 2005), the diagnosis for abuse also includes those who meet the diagnosis for dependence. In contrast, NSDUH follows DSM-IV guidelines and limits the definition of abuse to persons who do not meet the criteria for dependence. To make the NCS definition of abuse comparable with that of NSDUH, the rate for dependence must be subtracted from the rate for abuse. Rates of alcohol dependence or abuse and rates of illicit drug dependence or abuse were generally lower in NCS-R than in NSDUH (Kessler et al., 2005).

For further details, see the NCS Web site at <http://www.hcp.med.harvard.edu/ncs/>.

National Health and Nutrition Examination Survey (NHANES)

The National Health and Nutrition Examination Survey (NHANES) has assessed the health and nutritional status of children and adults in the United States since the 1960s through the use of both survey and physical examination components. It is sponsored by the National

Center for Health Statistics (NCHS) and began as a series of periodic surveys in which several years of data were combined into a single data release. Since 1999, it has been a continuous survey, with interview data collected each year for approximately 5,000 persons of all ages. The target population for NHANES is the civilian, noninstitutionalized population regardless of age. Data for 2009-2010 are the most currently available for public use; 2 years of data are combined to protect respondent confidentiality.

NHANES interviews are conducted in respondents' homes. NHANES also collects physical health measurements and data on sensitive topics through ACASI in mobile examination centers (MECs), which travel to locations throughout the United States. The NHANES MEC interview includes questions on alcohol, illicit drug, and tobacco use.

Both NSDUH and NHANES use complex cluster sample designs that affect the precision of estimates. In addition, the smaller sample sizes for NHANES (i.e., 5,000 per year vs. 67,500 per year for NSDUH) are likely to yield estimates that are less precise than those in NSDUH. The sources of nonresponse and coverage bias also differ for the two surveys. For example, NHANES respondents have to travel to a MEC to respond to the substance use items, which may eliminate homebound respondents or affect the participation of respondents with limited access to transportation.

Combined NHANES data from 1999 to 2004 indicated that 13.0 percent of youths aged 12 to 17 had smoked cigarettes in the past 30 days, 21.1 percent had used alcohol in the past 30 days, and 10.4 percent were past month binge alcohol users. An estimated 21.1 percent of youths had ever tried marijuana, and 2.4 percent had ever used cocaine (Fryar, Merino, Hirsch, & Porter, 2009). NSDUH estimates for youths aged 12 to 17 in 2002 to 2004 ranged from 11.9 to 13.0 percent for past month use of cigarettes, from 17.6 to 17.7 percent for past month alcohol use, and from 10.6 to 11.1 percent for past month binge alcohol use. Lifetime use of marijuana in 2002 to 2004 among youths ranged from 19.0 to 20.6 percent, and lifetime use of cocaine ranged from 2.4 to 2.7 percent.

For further details, see the NHANES Web site at <http://www.cdc.gov/nchs/nhanes.htm>.

National Health Interview Survey (NHIS)

The National Health Interview Survey (NHIS) is a continuous nationwide sample survey that collects data using personal household interviews through an interviewer-administered CAPI system. The survey is sponsored by the NCHS and provides national estimates of the health status and behaviors of the civilian, noninstitutionalized population, including cigarette smoking and alcohol use among persons aged 18 or older. NHIS data have been collected since 1957. In 2010, data were derived from three core components of the survey: the Family Core, which collects information from all family members aged 18 or older in each household; the Sample Adult Core, which collects information from one adult aged 18 or older in each family; and the Sample Child Core, which collects information on youths under age 18 from a knowledgeable family member, usually a parent, in households with a child. In 2010, NHIS data were based on 89,976 persons in the Family Core, 27,157 adults in the Sample Adult Core, and 11,277 children in the Sample Child Core (NCHS, Division of Health Interview Statistics, 2011).

For further details, see the NCHS Web site at <http://www.cdc.gov/nchs/nhis.htm>.

National Longitudinal Alcohol Epidemiologic Survey (NLAES) and National Epidemiologic Survey on Alcohol and Related Conditions (NESARC)

The National Longitudinal Alcohol Epidemiologic Survey (NLAES) was conducted in 1991 and 1992 by the U.S. Bureau of the Census for the National Institute on Alcohol Abuse and Alcoholism (NIAAA). Face-to-face, interviewer-administered interviews were conducted with 42,862 respondents aged 18 or older in the contiguous United States. Despite the survey name, the design was cross-sectional.

The National Epidemiologic Survey on Alcohol and Related Conditions (NESARC) was conducted in 2001 and 2002, also by the U.S. Bureau of the Census for NIAAA, using a computerized interviewer-administered interview. The NESARC sample was designed to make inferences for persons aged 18 or older in the civilian, noninstitutionalized population of the United States, including Alaska, Hawaii, and the District of Columbia, and including persons living in noninstitutional group quarters. NESARC was designed to be a longitudinal survey. The first wave was conducted in 2001 and 2002, with a final sample size of 43,093 respondents aged 18 or older. The second wave was conducted in 2004 and 2005 (Grant & Dawson, 2006). A 1-year data collection period for the next wave of the survey (NESARC-III) began in 2012 with a new sample of approximately 46,500 adults.

The study contains assessments of drug use, dependence, and abuse and associated mental disorders. NESARC included an extensive set of questions, based on DSM-IV criteria (APA, 1994), designed to assess the presence of symptoms of alcohol and drug dependence and abuse in persons' lifetimes and during the prior 12 months. In addition, DSM-IV diagnoses of major mental disorders were generated using the Alcohol Use Disorder and Associated Disabilities Interview Schedule-version 4 (AUDADIS-IV), which is a structured diagnostic interview that captures major DSM-IV axis I and axis II disorders.

Research indicates that (a) prevalence estimates for substance use were generally higher in NSDUH than in NESARC; (b) rates of past year substance use disorder (SUD) for cocaine and heroin use were higher in NSDUH than in NESARC; (c) rates of past year SUD for use of alcohol, marijuana, and hallucinogens were similar between NSDUH and NESARC; and (d) prevalence estimates for past year SUD conditional on past year use were substantially lower in NSDUH for the use of marijuana, hallucinogens, and cocaine (Gruca et al., 2007). A number of methodological factors might have contributed to such discrepancies, including privacy and anonymity (questions about sensitive topics in NSDUH are self-administered, while similar questions are interviewer administered in NESARC, which may have resulted in higher use estimates in NSDUH) and differences in SUD diagnostic instrumentation (which may have resulted in higher SUD prevalence among past year substance users in NESARC).

For further details about NLAES, see Stinson et al. (1998). For an overview of NESARC findings, see Caetano (2006).

National Longitudinal Study of Adolescent Health (Add Health)

The National Longitudinal Study of Adolescent Health (Add Health) was conducted to measure the effects of family, peer group, school, neighborhood, religious institution, and community influences on health risks, such as tobacco, drug, and alcohol use. Add Health was initiated in 1994 and supported by grants from the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) with cofunding from 21 other Federal agencies and foundations.

The study began in 1994-1995 (Wave I) with an in-school questionnaire administered to a nationally representative sample of students in grades 7 to 12 and followed up with an in-home interview. In Wave I, about 90,000 students in grades 7 to 12 were surveyed at 144 schools around the United States using brief, machine-readable questionnaires during a regular class period. Interviews also were conducted with about 20,000 students and their parents in the students' homes using a combined CAPI and ACASI design. In Wave II, conducted in 1996, about 15,000 students in grades 8 to 12 were interviewed a second time in their homes. In Wave III in 2001-2002, about 15,000 of the original Add Health respondents, then aged 18 to 26, were reinterviewed to investigate how adolescent experiences and behaviors are related to outcomes during the transition to adulthood. Wave IV was conducted in 2007-2008 when the approximately 15,000 respondents were aged 24 to 32. The study provides information on the use of alcohol, illicit drugs, and tobacco.

For further details, see the Add Health Web site at <http://www.cpc.unc.edu/projects/addhealth>.

Partnership Attitude Tracking Study (PATS)

The Partnership Attitude Tracking Study (PATS), an annual national research study that tracks attitudes about illegal drugs, is sponsored by the Partnership at Drugfree.org and the MetLife Foundation. PATS consists of two nationally representative samples—a teenage sample for students in grades 9 through 12 and a parent sample. Adolescents complete self-administered, machine-readable questionnaires during a regular class period with their teacher remaining in the room. The latest PATS surveys of teenagers and parents were conducted in 2011. The 2011 survey of adolescents included questions about use of cigarettes, alcohol, and illicit drugs. In 2011, 3,322 teenagers were surveyed nationwide in the 23rd wave of the survey conducted since 1987, and 821 parents or caregivers of children in grades 9 to 12 were surveyed (Partnership at Drugfree.org & MetLife Foundation, 2012).

In general, NSDUH estimates of substance use prevalence for adolescents are lower than PATS estimates for youths in that age group. In 2011, for example, PATS estimates of marijuana use among adolescents in grades 9 through 12 were 47 percent for lifetime use and 27 percent for use in the past month (Partnership at Drugfree.org & MetLife Foundation, 2012). Corresponding estimates of marijuana use from NSDUH for grades 9 through 12 were 29.3 percent for lifetime use and 13.3 percent for past month use (Table C.2). The differences in prevalence estimates are likely to be due to the different study designs. The youth portion of PATS is a school-based survey, which may elicit more reporting of sensitive behaviors than the home-based NSDUH.

For further details, see the Partnership at Drugfree.org Web site at <http://www.drugfree.org/>.

Youth Risk Behavior Survey (YRBS)

The Youth Risk Behavior Survey (YRBS) is a component of the CDC's Youth Risk Behavior Surveillance System (YRBSS), which measures the prevalence of six priority health risk behavior categories: (a) behaviors that contribute to unintentional injuries and violence; (b) tobacco use; (c) alcohol and other drug use; (d) sexual behaviors that contribute to unintended pregnancy and sexually transmitted diseases, including human immunodeficiency virus infection; (e) unhealthy dietary behaviors; and (f) physical inactivity. The YRBSS includes national, State, territorial, tribal, and local school-based surveys of high school students conducted every 2 years. The national school-based survey uses a three-stage cluster sample design to produce a nationally representative sample of students in grades 9 through 12 who attend public and private schools. The State and local surveys use a two-stage cluster sample design to produce representative samples of public school students in grades 9 through 12 in their jurisdictions. The YRBS is conducted during the spring, with students completing a self-administered, machine-readable questionnaire during a regular class period. The latest YRBS was conducted in 2011. For the 2011 national YRBS, 15,425 usable questionnaires were obtained in 158 schools.

In general, the YRBS school-based survey has found higher rates of substance use for youths than those found in NSDUH (Table C.2).³¹ The lower prevalence rates in NSDUH are likely due to the differences in study design. As in the case of comparisons with estimates from the MTF, the lower prevalences in NSDUH may be due to more underreporting in the household setting, as compared with the YRBS school setting, and some overreporting in the school settings.

Similar to other school-based surveys, the population of inference for the YRBS is the population of adolescents who are in school, specifically those in the 9th through 12th grades. Consequently, the YRBS does not include data from dropouts. The YRBS makes follow-up attempts to obtain data from youths who were absent on the day of survey administration, but nevertheless does not obtain complete coverage of these youths. For these reasons, YRBS data are not intended to be used for making inferences about the adolescent population of the United States as a whole.

For further details, see the CDC Web site at <http://www.cdc.gov/HealthyYouth/yrbs/>.

C.2 Surveys of Populations Not Covered by NSDUH

Department of Defense Survey of Health Related Behaviors Among Active Duty Military Personnel

The 2008 Department of Defense Survey of Health Related Behaviors Among Active Duty Military Personnel was the 10th in a series of studies conducted since 1980. The sample

³¹ To examine estimates that are comparable with YRBS data, NSDUH estimates presented in Table C.2 are based on data collected in the first 6 months of the survey year and are subset to ages 12 to 20.

consisted of 28,546 active-duty Armed Forces personnel worldwide who anonymously completed self-administered questionnaires that assessed substance use and other health behaviors. Members of the Coast Guard were included for the first time in the 2008 survey (Bray et al., 2009). The 2011 survey was fielded in August 2011 and included onsite and Internet survey administrations (Assistant Secretary of Defense for Health Affairs, 2011). The survey provides information about the use of alcohol, illicit drugs, and tobacco.

In recent administrations of this survey, comparisons with NSDUH data have consistently shown that, even after accounting for demographic differences between the military and civilian populations, the military personnel had higher rates of heavy alcohol use than their civilian counterparts, similar rates of cigarette use, and lower rates of illicit drug use.

Surveys of Inmates in State and Federal Correctional Facilities (SISCF, SIFCF)

The Survey of Inmates in State Correctional Facilities (SISCF) and the Survey of Inmates in Federal Correctional Facilities (SIFCF) have provided nationally representative data on State prison inmates and sentenced Federal inmates held in federally owned and operated facilities. The Survey of State Inmates was conducted in 1974, 1979, 1986, 1991, 1997, and 2004, and the Survey of Federal Inmates in 1991, 1997, and 2004. The 2004 SISCF was conducted for the Bureau of Justice Statistics (BJS) by the U.S. Census Bureau, which also conducted the SIFCF for the BJS and the Federal Bureau of Prisons. Both surveys provide information about current offense and criminal history, family background and personal characteristics, prior drug and alcohol use and treatment, gun possession, and prison treatment, programs, and services. The surveys are the only national source of detailed information on criminal offenders, particularly special populations such as drug and alcohol users and offenders who have mental health problems. Systematic random sampling was used to select the inmates, and the 2004 surveys of State and Federal inmates were administered through CAPI. In 2004, 14,499 State prisoners in 287 State prisons and 3,686 Federal prisoners in 39 Federal prisons were interviewed.

Prior drug use among State prisoners remained stable on all measures between 1997 and 2004, while the percentage of Federal inmates who reported prior drug use rose on most measures (Mumola & Karberg, 2006). For the first time, half of Federal inmates reported drug use in the month before their offense. In 2004, measures of drug dependence and abuse based on criteria in DSM-IV (APA, 1994) were introduced, and 53 percent of the State and 45 percent of Federal prisoners met the DSM-IV criteria for drug abuse or dependence. The survey results indicate substantially higher rates of drug use among State and Federal prisoners as compared with NSDUH's rates for the general household population.

For further details, see BJS's "All Data Collections" Web page at <http://bjs.ojp.usdoj.gov/index.cfm?ty=dca>.

Table C.1 Use of Specific Substances in Lifetime, Past Year, and Past Month among 8th, 10th, and 12th Graders in MTF and NSDUH: Percentages, 2010 and 2011

Drug/Current Grade Level	MTF Lifetime (2010)	MTF Lifetime (2011)	MTF Past Year (2010)	MTF Past Year (2011)	MTF Past Month (2010)	MTF Past Month (2011)	NSDUH Lifetime (2010)	NSDUH Lifetime (2011)	NSDUH Past Year (2010)	NSDUH Past Year (2011)	NSDUH Past Month (2010)	NSDUH Past Month (2011)
Marijuana												
8th Grade	17.3	16.4	13.7	12.5	8.0	7.2	8.3	8.7	7.1	6.6	3.1	3.3

Appendix E: List of Contributors

This National Survey on Drug Use and Health (NSDUH) report was prepared by the Center for Behavioral Health Statistics and Quality (CBHSQ), Substance Abuse and Mental Health Services Administration (SAMHSA), U.S. Department of Health and Human Services (HHS), and by RTI International (a trade name of Research Triangle Institute), Research Triangle Park, North Carolina. Work by RTI was performed under Contract No. HHSS283200800004C.

Contributors at SAMHSA listed alphabetically, with chapter authorship noted, include Peggy Barker, Jonaki Bose (Chapter 1), Joseph Gfroerer (Chapter 8), Beth Han (Chapter 7), Sarra L. Hedden, Michael Jones (Chapter 4), Joel Kennet (Chapter 3), Rachel Lipari (Chapter 6), Pradip Muhuri (Chapter 5), Dicy Painter, and Peter Tice (Project Officer) (Chapter 2).

Contributors and reviewers at RTI listed alphabetically include Jeremy Aldworth, Heather Archambault, Kat Asman, Stephanie Barnett, Ellen Bishop, Pinliang (Patrick) Chen, James R. Chromy, Jennifer Cooney, Elizabeth Copello, G. Lance Couzens, Devon S. Cribb, Christine Davies, Teresa R. Davis, Ralph E. Folsom, Jr., Misty S. Foster, Peter Frechtel, Julia Gable, Rebecca A. Granger, Wafa Handley, Erica Hirsch, David Cunningham Hunter, Ilona Johnson, Greta Kilmer, Phillip Kott, Larry A. Kroutil, Dan Liao, Peilan Chen Martin, Martin Meyer, Andrew Moore, Katherine B. Morton, N. Ben Neely, Scott Novak, Lisa E. Packer, Michael R. Pemberton, Jeremy Porter, Harley Rohloff, Neeraja S. Sathe, Victoria Scott, Kathryn Spagnola, Thomas G. Virag (Project Director), Jiantong (Jean) Wang, and Lauren Klein Warren.

Also at RTI, report and Web production staff listed alphabetically include Teresa F. Bass, Debbie F. Bond, Kimberly Cone, Valerie Garner, Anne Gering, E. Andrew Jessup, Tayo Jolaoso, Shari B. Lambert, Farrah Bullock Mann, Brenda K. Porter, Pamela Couch Prevatt, Roxanne Snaauw, Marissa R. Straw, Richard S. Straw, Pamela Tuck, and Cheryl Velez.
